Preface **127**

1 Introduction **129**

2 Interrupts **131**

2.1 ARM Cortex A8 Interrupts 132
2.2 ARM Cortex M3 Interrupts 135
2.3 PRUSS Interrupts 137
2.4 EDMA Events 139
2.5 Crypto DMA Events 142
2.6 PWM Events 144
2.7 INTCPS Registers 144
2.7.1 INTCPS_REVISION Register (offset = 0h) [reset = 0h] 151
2.7.2 INTCPS_FIQ_PRIORITY Register (offset = 64h) [reset = 0h] 152
2.7.3 INTCPS_THRESHOLD Register (offset = 68h) [reset = 0h] 153
2.7.4 INTCPS_ITR0 Register (offset = 80h) [reset = 0h] 154
2.7.5 INTCPS_MIR0 Register (offset = 84h) [reset = 0h] 155
2.7.6 INTCPS_MIR_CLEAR0 Register (offset = 88h) [reset = 0h] 156
2.7.7 INTCPS_MIR_SET0 Register (offset = 8Ch) [reset = 0h] 157
2.7.8 INTCPS_ISR_SET0 Register (offset = 90h) [reset = 0h] 158
2.7.9 INTCPS_ISR_CLEAR0 Register (offset = 94h) [reset = 0h] 159
2.7.10 INTCPS_PENDING_IRQ0 Register (offset = 98h) [reset = 0h] 160
2.7.11 INTCPS_PENDING_FIQ0 Register (offset = 9Ch) [reset = 0h] 161
2.7.12 INTCPS_SYSCONFIG Register (offset = 10h) [reset = 0h] 162
2.7.13 INTCPS_ITR1 Register (offset = A0h) [reset = 0h] 163
2.7.14 INTCPS_MIR1 Register (offset = A4h) [reset = 0h] 164
2.7.15 INTCPS_MIR_CLEAR1 Register (offset = A8h) [reset = 0h] 165
2.7.16 INTCPS_MIR_SET1 Register (offset = ACh) [reset = 0h] 166
2.7.17 INTCPS_ISR_SET1 Register (offset = B0h) [reset = 0h] 167
2.7.18 INTCPS_ISR_CLEAR1 Register (offset = B4h) [reset = 0h] 168
2.7.19 INTCPS_PENDING_IRQ1 Register (offset = B8h) [reset = 0h] 169
2.7.20 INTCPS_PENDING_FIQ1 Register (offset = BCh) [reset = 0h] 170
2.7.21 INTCPS_ITR2 Register (offset = C0h) [reset = 0h] 171
2.7.22 INTCPS_MIR2 Register (offset = C4h) [reset = 0h] 172
2.7.23 INTCPS_SYSSTATUS Register (offset = 14h) [reset = 0h] 173
2.7.24 INTCPS_MIR_CLEAR2 Register (offset = C8h) [reset = 0h] 174
2.7.25 INTCPS_MIR_SET2 Register (offset = CCh) [reset = 0h] 175
2.7.26 INTCPS_ISR_SET2 Register (offset = D0h) [reset = 0h] 176
2.7.27 INTCPS_ISR_CLEAR2 Register (offset = D4h) [reset = 0h] 177
2.7.28 INTCPS_PENDING_IRQ2 Register (offset = D8h) [reset = 0h] 178
2.7.29 INTCPS_PENDING_FIQ2 Register (offset = DCh) [reset = 0h] 179
2.7.30 INTCPS_ITR3 Register (offset = E0h) [reset = 0h] 180
2.7.31 INTCPS_MIR3 Register (offset = E4h) [reset = 0h] 181
2.7.32 INTCPS_MIR_CLEAR3 Register (offset = E8h) [reset = 0h] 182
2.7.33 INTCPS_MIR_SET3 Register (offset = ECh) [reset = 0h] 183
2.7.34 INTCPS_ISR_SET3 Register (offset = F0h) [reset = 0h] 184
2.7.35 INTCPS_ISR_CLEAR3 Register (offset = F4h) [reset = 0h] 185

21-19. Audio Mute Control Register (AMUTE) Field Descriptions 2735
21-20. Digital Loopback Control Register (DLBCTL) Field Descriptions 2737
21-21. Digital Mode Control Register (DITCTL) Field Descriptions 2738
21-22. Receiver Global Control Register (RGBLCTL) Field Descriptions 2739
21-23. Receive Format Unit Bit Mask Register (RMASK) Field Descriptions 2740
21-24. Receive Bit Stream Format Register (RFMT) Field Descriptions 2741
21-25. Receive Frame Sync Control Register (AFSRCTL) Field Descriptions 2743
21-26. Receive Clock Control Register (ACLKRCTL) Field Descriptions 2744
21-27. Receive High-Frequency Clock Control Register (AHCLKRCTL) Field Descriptions 2745
21-28. Receive TDM Time Slot Register (RTDM) Field Descriptions 2746
21-29. Receiver Interrupt Control Register (RINTCTL) Field Descriptions 2747
21-30. Receiver Status Register (RSTAT) Field Descriptions 2748
21-31. Current Receive TDM Time Slot Registers (RSLOT) Field Descriptions 2749
21-32. Receive Clock Check Control Register (RCLKCHK) Field Descriptions 2750
21-33. Receiver DMA Event Control Register (REVTCTL) Field Descriptions 2751
21-34. Transmitter Global Control Register (XGBLCTL) Field Descriptions 2752
21-35. Transmit Format Unit Bit Mask Register (XMASK) Field Descriptions 2753
21-36. Transmit Bit Stream Format Register (XFMT) Field Descriptions 2754
21-37. Transmit Frame Sync Control Register (AFSXCTL) Field Descriptions 2756
21-38. Transmit Clock Control Register (ACLKXCTL) Field Descriptions 2757
21-39. Transmit High-Frequency Clock Control Register (AHCLKXCTL) Field Descriptions 2758
21-40. Transmit TDM Time Slot Register (XTDM) Field Descriptions 2759
21-41. Transmitter Interrupt Control Register (XINTCTL) Field Descriptions 2760
21-42. Transmitter Status Register (XSTAT) Field Descriptions 2761
21-43. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions 2762
21-44. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions 2763
21-45. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions 2764
21-46. Serializer Control Registers (SRCTL*n*) Field Descriptions 2765
21-47. Write FIFO Control Register (WFIFOCTL) Field Descriptions 2768
21-48. Write FIFO Status Register (WFIFOSTS) Field Descriptions 2769
21-49. Read FIFO Control Register (RFIFOCTL) Field Descriptions 2770
21-50. Read FIFO Status Register (RFIFOSTS) Field Descriptions 2771
22-1. DCAN Connectivity Attributes 2775
22-2. DCAN Clock Signals 2775
22-3. DCAN Pin List 2775
22-4. Initialization of a Transmit Object 2791
22-5. Initialization of a single Receive Object for Data Frames 2791
22-6. Initialization of a Single Receive Object for Remote Frames 2792

2.1 ARM Cortex A8 Interrupts

Table 2-1. ARM Cortex A8 Interrupts

Int Number	Acronym/name	Source	Signal Name
0	EMUINT	MPU Subsystem Internal	Emulation interrupt (EMUICINTR)
1	COMMTX	MPU Subsystem Internal	CortexA8 COMMTX
2	COMMRX	MPU Subsystem Internal	CortexA8 COMMRX
3	BENCH	MPU Subsystem Internal	CortexA8 NPMUIRQ
4	ELM_IRQ	ELM	Sinterrupt (Error location process completion)
5	SSM_WFI_IRQ	MPU Subsystem Internal (SSM)	MPU s/s Secure State Machine Wait for Interrupt (WFI) tracking mechanism
6	SSM_IRQ	MPU Subsystem Internal (SSM)	MPU s/s Secure State Machine interrupt generation for Public FIQ support
7	NMI	External Pin (Primary Input)	nmi_int
8	SEC_EVNT	Firewalls	security_events_irq
9	L3DEBUG	L3	l3_FlagMux_top_FlagOut1
10	L3APPINT	L3	l3_FlagMux_top_FlagOut0
11	PRCMINT	PRCM	irq_mpu
12	EDMACOMPINT	TPCC	tpcc_int_pend_po0
13	EDMAMPERR	TPCC	tpcc_mpint_pend_po
14	EDMAERRINT	TPCC	tpcc_errint_pend_po
15	WDT0INT	WDTIMER0	PO_INT_PEND
16	ADC_TSC_GENINT	ADC_TSC	gen_intr_pend
17	USBSSINT	USBSS	usbss_intr_pend
18	USBINT0	USBSS	usb0_intr_pend
19	USBINT1	USBSS	usb1_intr_pend
20	PRUSS1_EVTOUT0	pr1_host[0] output/events exported from PRUSS1	pr1_host_intr0_intr_pend
21	PRUSS1_EVTOUT1	pr1_host[1] output/events exported from PRUSS1	pr1_host_intr1_intr_pend
22	PRUSS1_EVTOUT2	pr1_host[2] output/events exported from PRUSS1	pr1_host_intr2_intr_pend
23	PRUSS1_EVTOUT3	pr1_host[3] output/events exported from PRUSS1	pr1_host_intr3_intr_pend
24	PRUSS1_EVTOUT4	pr1_host[4] output/events exported from PRUSS1	pr1_host_intr4_intr_pend
25	PRUSS1_EVTOUT5	pr1_host[5] output/events exported from PRUSS1	pr1_host_intr5_intr_pend
26	PRUSS1_EVTOUT6	pr1_host[6] output/events exported from PRUSS1	pr1_host_intr6_intr_pend
27	PRUSS1_EVTOUT7	pr1_host[7] output/events exported from PRUSS1	pr1_host_intr7_intr_pend
28	MMCSD1INT	MMCSD1	SINTERRUPTN
29	MMCSD2INT	MMCSD2	SINTERRUPTN
30	I2C2INT	I2C2	POINTRPEND
31	eCAP0INT	eCAP0 event/interrupt	ecap_intr_intr_pend
32	GPIOINT2A	GPIO 2	POINTRPEND1
33	GPIOINT2B	GPIO 2	POINTRPEND2
34	USBWAKEUP	USBSS	slv0p_Swakeup
36	LCDCINT	LCDC	lcd_irq

2.7 INTCPS Registers

Table 2-7 lists the memory-mapped registers for the INTCPS. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 2-7 should be considered as reserved locations and the register contents should not be modified.

Table 2-7. INTCPS REGISTERS

Offset	Acronym	Register Description	Section
0h	INTCPS_REVISION	This register contains the IP revision code	Section 2.7.1
64h	INTCPS_FIQ_PRIORITY	This register supplies the currently active FIQ priority level	Section 2.7.2
68h	INTCPS_THRESHOLD	This register sets the priority threshold	Section 2.7.3
80h	INTCPS_ITR0	This register shows the raw interrupt input status before masking	Section 2.7.4
84h	INTCPS_MIR0	This register contains the interrupt mask	Section 2.7.5
88h	INTCPS_MIR_CLEAR0	This register is used to clear the interrupt mask bits.	Section 2.7.6
8Ch	INTCPS_MIR_SET0	This register is used to set the interrupt mask bits.	Section 2.7.7
90h	INTCPS_ISR_SET0	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 2.7.8
94h	INTCPS_ISR_CLEAR0	This register is used to clear the software interrupt bits	Section 2.7.9
98h	INTCPS_PENDING_IRQ0	This register contains the IRQ status after masking	Section 2.7.10
9Ch	INTCPS_PENDING_FIQ0	This register contains the FIQ status after masking	Section 2.7.11
10h	INTCPS_SYSCONFIG	This register controls the various parameters of the OCP interface	Section 2.7.12
A0h	INTCPS_ITR1	This register shows the raw interrupt input status before masking	Section 2.7.13
A4h	INTCPS_MIR1	This register contains the interrupt mask	Section 2.7.14
A8h	INTCPS_MIR_CLEAR1	This register is used to clear the interrupt mask bits.	Section 2.7.15
ACh	INTCPS_MIR_SET1	This register is used to set the interrupt mask bits.	Section 2.7.16
B0h	INTCPS_ISR_SET1	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 2.7.17
B4h	INTCPS_ISR_CLEAR1	This register is used to clear the software interrupt bits	Section 2.7.18
B8h	INTCPS_PENDING_IRQ1	This register contains the IRQ status after masking	Section 2.7.19
BCh	INTCPS_PENDING_FIQ1	This register contains the FIQ status after masking	Section 2.7.20
C0h	INTCPS_ITR2	This register shows the raw interrupt input status before masking	Section 2.7.21
C4h	INTCPS_MIR2	This register contains the interrupt mask	Section 2.7.22
14h	INTCPS_SYSSTATUS	This register provides status information about the module	Section 2.7.23
C8h	INTCPS_MIR_CLEAR2	This register is used to clear the interrupt mask bits.	Section 2.7.24
CCh	INTCPS_MIR_SET2	This register is used to set the interrupt mask bits.	Section 2.7.25
D0h	INTCPS_ISR_SET2	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 2.7.26
D4h	INTCPS_ISR_CLEAR2	This register is used to clear the software interrupt bits	Section 2.7.27
D8h	INTCPS_PENDING_IRQ2	This register contains the IRQ status after masking	Section 2.7.28
DCh	INTCPS_PENDING_FIQ2	This register contains the FIQ status after masking	Section 2.7.29
E0h	INTCPS_ITR3	This register shows the raw interrupt input status before masking	Section 2.7.30
E4h	INTCPS_MIR3	This register contains the interrupt mask	Section 2.7.31
E8h	INTCPS_MIR_CLEAR3	This register is used to clear the interrupt mask bits.	Section 2.7.32
ECh	INTCPS_MIR_SET3	This register is used to set the interrupt mask bits.	Section 2.7.33
F0h	INTCPS_ISR_SET3	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 2.7.34
F4h	INTCPS_ISR_CLEAR3	This register is used to clear the software interrupt bits	Section 2.7.35
F8h	INTCPS_PENDING_IRQ3	This register contains the IRQ status after masking	Section 2.7.36
FCh	INTCPS_PENDING_FIQ3	This register contains the FIQ status after masking	Section 2.7.37

2.7.161 INTCPS_ILR120 Register (offset = 2E0h) [reset = 0h]

These registers contain the priority for the interrupts and the FIQ/IRQ steering.

INTCPS_ILR120 is shown in Figure 2-161 and described in Table 2-168.

2.7.167 INTCPS_PROTECTION Register (offset = 4Ch) [reset = 0h]

This register controls protection of the other registers. This register can only be accessed in priviledged mode, regardless of the curent value of the protection bit.

INTCPS_PROTECTION is shown in Figure 2-167 and described in Table 2-174.

(1) The Wakeup M3 may access the UMEM and DMEM using the L4_WKUP (OCP Bus) or it may use its direct buses, by accessing address 0x00000000 – 0x00081FFF.
(2) These addresses correspond to L3 regions. These are reserved regions with respect to Wakeup M3.
(3) Accessing these bit-band alias regions results in an access to the corresponding bit-band region.
(4) Peripherals located on L4 Wakeup Bus can be accessed by Wakeup M3.

(1) These addresses correspond to L3 region for which the Wakeup M3 has no connectivity. Access to these regions will result in a fault.

(2) Some memory locations map to M3 bit-band alias regions – access to these locations will result in an access to the corresponding bit-band region which maps to an L3 region inaccessible to the Wakeup. Accesses to these regions will result in a fault.

(3) Peripherals located in these regions are accessible by L3 Initiators.

(4) The Wakeup M3 may access the I/D MEM and SMEM using the L4_WKUP (through system bus AHB2OCP interface), or it may use its direct buses (ICode, Dcode), by accessing address 0x00000000 – 0x004FFFFF.

4.1 Introduction

The Programmable Real-time Unit Subsystem (PRUSS) consists of dual 32-bit RISC cores (Programmable Real-Time Units, or PRUs), shared, data, and instruction memories, internal peripheral modules, and an interrupt controller (INTC). The programmable nature of the PRUs, along with their access to pins and events, provide flexibility in implementing custom peripheral interfaces, fast real-time responses, power saving techniques, specialized data handling and DMA operations, and in offloading tasks from the other processor cores of the system-on-chip (SoC).

Figure 4-1 shows the PRUSS details. The subsystem available on this device is the next-generation PRUSS (PRUSSv2). Compared to the previous generation available on AM1x and OMAP-L13x, this version includes the following enhancements:

- Additional data memory (7.5 KB) and instruction memory (4KB)
- 12 KB Shared RAM
- Enhanced GPIO (EGPIO), adding serial, parallel, and MII capture of the PRU input/output pins
- Scratch pad (SPAD) shared by the PRU cores
- Multiplier with optional accumulation (MAC)
- Internal peripheral modules (UART, eCAP, MII_RT, MDIO, and IEP)

Similar to the previous generation, the PRUs have access to all resources on the SoC through the Master OCP port, and the external Host processors can access the PRUSS resources through the Slave OCP port. The Switched Central Resource (SCR) connects the various internal and external masters to the resources inside the PRUSS. The INTC handles system input events and posts events back to the device-level host CPU.

The PRU cores are programmed with a small, deterministic instruction set. Each PRU can operate independently or in coordination with each other and can also work in coordination with the device-level host CPU. This interaction between processors is determined by the nature of the firmware loaded into the PRU's instruction memory.

Figure 4-1. Block Diagram

4.1.1 Features

The PRU subsystem includes the following main features:

- Two PRUs each with:
  - 8KB program memory
  - 8KB data memory

Copyright © 2011, Texas Instruments Incorporated

  - High Performance OCP Master port for accessing external memories
  - Enhanced GPIO with async capture and serial support
  - Multiplier with optional Accumulation
- One Scratch Pad memory and broadside direct connect
  - 3 Banks of 30 32-bit registers
- 12 KB general purpose shared memory
- One Interrupt Controller (INTC)
  - Up to 64 input events supported
  - Interrupt mapping to 10 interrupt channels
  - 10 Host interrupts (2 to PRU0 and PRU1, 8 output to chip level)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- 16 software Events generation by 2 PRUs
- One Ethernet MII_RT module with 2 MII ports and configurable connections to PRUs
- One MDIO Port
- One Industrial Ethernet Peripheral (IEP) to manage/generate Industrial Ethernet functions
  - 1 Industrial Ethernet timer with 7/9 capture and 8 compare events
  - 2 Industrial Ethernet sync signals
  - 2 Industrial Ethernet 16-bit watchdog timers
  - Industrial Ethernet digital IOs
- One 16550-compatible UART with a dedicated 192 MHz clock
- One Enhanced Capture Module (ECAP)
- Flexible power management support
- Integrated switched central resource (SCR) bus for connecting the various internal and external masters to the resources inside the PRUSS
- OCP Slave port for external masters to access PRUSS memories
- Optional address translation for PRU transaction to External Host
- All memories within the PRUSS support parity

4.2 Integration

4.3 Functional Description

4.4 Use Cases

4.5 PRUSS_INTC Registers

Table 4-1 lists the memory-mapped registers for the PRUSS_INTC. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 4-1 should be considered as reserved locations and the register contents should not be modified.

4.7 PRUSS_PRU_DEBUG Registers

Table 4-75 lists the memory-mapped registers for the PRUSS_PRU_DEBUG. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 4-75 should be considered as reserved locations and the register contents should not be modified.

5.5 Registers

5.5.1 SGX530_MMAV10GS70 Registers

Table 5-1 lists the memory-mapped registers for the SGX530_MMAV10GS70. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 5-1 should be considered as reserved locations and the register contents should not be modified.

Table 5-1. SGX530_MMAV10GS70 REGISTERS

Offset	Acronym	Register Description	Section
0h	EUR_CR_CLKGATECTL	Core module clock gating controls: allows clocks to be forced off, forced on or operate under automatic pipeline activity based clock gating.	Section 5.5.1.1
64h	EUR_CR_PERF_COUNTER8	Performance counter status register	Section 5.5.1.2
400h	EUR_CR_PIXELBE	The PixelBE modules format the pixel data before writing to memory, this register contains global control signals.	Section 5.5.1.3
404h	EUR_CR_ISP_RENDER	The Image Synthesis Processor can be configured to operate in 3 different render modes	Section 5.5.1.4
408h	EUR_CR_ISP_RGN_BASE	This register defines the base address in memory of the Region Header reads by the ISP. Region headers are the first part of the display list and contain an entry per tile with information on global setup and a link address to parameters.	Section 5.5.1.5
40Ch	EUR_CR_ISP_RENDBOX1	When the render type is set to Fast 2D Render or Fast Scale Render, no region headers are read from memory. Instead, region headers are internally generated for all tiles enclosed in the bounding box defined by this register and the EUR_CR_ISP_RENDBOX2 register.	Section 5.5.1.6
410h	EUR_CR_ISP_RENDBOX2	When the render type is set to Fast 2D Render or Fast Scale Render, no region headers are read from memory. Instead, region headers are internally generated for all tiles enclosed in the bounding box defined by this register and the EUR_CR_ISP_RENDBOX1 register.	Section 5.5.1.7
414h	EUR_CR_ISP_IPFMISC	Global control register for the ISP parameter fetch.	Section 5.5.1.8
418h	EUR_CR_ISP_OGL_MODE	Global control register which modifies the pixel sample position to comply with OGL requirements.	Section 5.5.1.9
41Ch	EUR_CR_ISP_PERPENDICULAR		Section 5.5.1.10
420h	EUR_CR_ISP_CULLVALUE		Section 5.5.1.11
424h	EUR_CR_ISP_DBIAS		Section 5.5.1.12
428h	EUR_CR_ISP_START_RENDER	Any write to this register starts a 3D Render.	Section 5.5.1.13
42Ch	EUR_CR_3D_AA_MODE	Indicates to the 3D pipeline whether anti-aliasing is enabled or disabled	Section 5.5.1.14
430h	EUR_CR_ISP_BREAK	Object breakpoints can be inserted by the driver to interrupt a render part way and then resume the render from the point of interrupt at a later time, this register controls what happens when a breakpoint has been encountered.	Section 5.5.1.15
434h	EUR_CR_ISP_3DCONTEXT		Section 5.5.1.16
438h	EUR_CR_ISP_FPU		Section 5.5.1.17
43Ch	EUR_CR_TSP_PARAMETER_CACHE		Section 5.5.1.18
440h	EUR_CR_TSP_PARAMETER_FETCH		Section 5.5.1.19
480h	EUR_CR_ISP_ZLSCTL	Image Synthesis Processor Z Load/Store and format global control register	Section 5.5.1.20
484h	EUR_CR_ISP_ZLOAD_BASE	This register defines the base address in memory of the Z Buffer base address to load into the ISP for non-compressed ZLS formats.	Section 5.5.1.21

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Table 5-1. SGX530_MMAV10GS70 REGISTERS (continued)

Offset	Acronym	Register Description	Section
488h	EUR_CR_ISP_ZSTORE_BASE	This register defines the base address in memory of the Z Buffer base address to store data from the ISP for non-compressed ZLS formats.	Section 5.5.1.22
48Ch	EUR_CR_ISP_STENCIL_LOAD_BASE	This register defines the base address in memory of the Stencil Buffer base address to load into the ISP for Int24 and IEEE ZLS formats. This alternate stencil buffer base address is selectable based on the enable bit.	Section 5.5.1.23
490h	EUR_CR_ISP_STENCIL_STORE_BASE	This register defines the base address in memory of the Stencil Buffer base address to store data from the ISP for Int24 and IEEE ZLS formats. This alternate stencil buffer base address is selectable based on the enable bit.	Section 5.5.1.24
494h	EUR_CR_ISP_VISTEST_CTRL	This register can be used to reset the results of the 8 visibility test results. Write a 1 to the required bit field to clear the result register	Section 5.5.1.25
498h	EUR_CR_ISP_VISTEST_VISIBLE0		Section 5.5.1.26
49Ch	EUR_CR_ISP_VISTEST_VISIBLE1		Section 5.5.1.27
4A0h	EUR_CR_ISP_VISTEST_VISIBLE2		Section 5.5.1.28
4A4h	EUR_CR_ISP_VISTEST_VISIBLE3		Section 5.5.1.29
4A8h	EUR_CR_ISP_VISTEST_VISIBLE4		Section 5.5.1.30
4ACh	EUR_CR_ISP_VISTEST_VISIBLE5		Section 5.5.1.31
4B0h	EUR_CR_ISP_VISTEST_VISIBLE6		Section 5.5.1.32
4B4h	EUR_CR_ISP_VISTEST_VISIBLE7		Section 5.5.1.33
4B8h	EUR_CR_ISP_BGOBJDEPTH	The ISP operates by comparing depth values of incoming objects with the results of previous depth compares, in order to make sure there are no un-initialised values at the start of the tile or to cover pixels where there are no objects in the scene a default background object is configured under register control. This register provides the floating point depth value for this background object.	Section 5.5.1.34
4BCh	EUR_CR_ISP_BGOBJ	The ISP operates by comparing depth values of incoming objects with the results of previous depth compares, in order to make sure there is no un-initialised values at the start of the tile or to cover pixels where there are no objects in the scene a default background object is configured under register control. This register provides tag, mask and stencil information for this background object.	Section 5.5.1.35
4C4h	EUR_CR_ISP_BGOBJTAG	The ISP operates by comparing depth values of incoming objects with the results of previous depth compares, in order to make sure there are no unitialised values at the start of the tile or to cover pixels where there are no objects in the scene a default background object is configured under register control. This register provides TSP and Vertex information for this background object.	Section 5.5.1.36
4C8h	EUR_CR_ISP_MULTISAMPLECTL	This applies when anti-aliasing is enabled. This is used by the ISP to adjust the sample positions.	Section 5.5.1.37
4CCh	EUR_CR_ISP_SIG1		Section 5.5.1.38
4D0h	EUR_CR_ISP_SIG2		Section 5.5.1.39
4D4h	EUR_CR_ISP_SIG3		Section 5.5.1.40

DRAFT ONLY

Table 5-1. SGX530_MMAV10GS70 REGISTERS (continued)

Offset	Acronym	Register Description	Section
4D8h	EUR_CR_ISP_SIG4		Section 5.5.1.41
4DCh	EUR_CR_ISP_TAGCTRL		Section 5.5.1.42
4E0h	EUR_CR_ISP_STATUS1		Section 5.5.1.43
4E4h	EUR_CR_ISP_STATUS2		Section 5.5.1.44
4E8h	EUR_CR_ISP_DEPTHSORT		Section 5.5.1.45
4ECh	EUR_CR_PIXELBE_EMIT	This register indicates if the PixelBE would stall the USE if there were another emit. '1' indicates that the PixelBE would stall the USE. '0' indicates that the PixelBE would not stall the USE.	Section 5.5.1.46
80h	EUR_CR_SOFT_RESET	Soft reset control register which drives all modules except the register bank. Write a '1' to reset and a '0' to clear	Section 5.5.1.47
600h	EUR_CR_DPM_3D_PAGE_TABLE_BASE	Effective on load 3D context, this register defines the base address of the page table being referenced in the process of de-allocating pages during a 3D render.	Section 5.5.1.48
604h	EUR_CR_DPM_3D_FREE_LIST	Between the FREE_LIST_HEAD and FREE_LIST_TAIL there must be a valid chain of linked pages. The linked list is stored in memory, at the EUR_CR_DPM_3D_PAGE_TABLE_BASE_ADDRESS and is effective on load 3D context.	Section 5.5.1.49
614h	EUR_CR_DPM_PDS_PAGE_THRESHOLD	This is the threshold in 4KB pages at which the hardware will stop double buffering the internal vertex processing buffers (and drop to single buffered mode). This is required in order to guarantee that a 3D render can run when running in dynamic parameter management mode. It should be set to 0.25MB less (in pages 0x40) than the ZLS threshold (or 0 in very small memory systems).	Section 5.5.1.50
618h	EUR_CR_DPM_TA_ALLOC_PAGE_TABLE_BASE	Effective on Loading the TA Page Table Context, this register defines the base address of the page table being referenced in the process of allocating pages by the TE and MTE.	Section 5.5.1.51
61Ch	EUR_CR_DPM_TA_ALLOC_FREE_LIST	Between the FREE_LIST_HEAD and FREE_LIST_TAIL there must be a valid chain of linked pages. The linked list is stored in memory, at the EUR_CR_DPM_TA_ALLOC_PAGE_TABLE_BASE_ADDRESS and is effective on Loading the TA Page Table Context.	Section 5.5.1.52
620h	EUR_CR_DPM_TA_PAGE_THRESHOLD		Section 5.5.1.53
624h	EUR_CR_DPM_ZLS_PAGE_THRESHOLD		Section 5.5.1.54
628h	EUR_CR_DPM_TA_GLOBAL_LIST		Section 5.5.1.55
62Ch	EUR_CR_DPM_STATE_TABLE_BASE	Effective immediately, this register defines the base address of the state table when it is read and written to/from memory. The state table itself contains the head, tail and number of pages allocated to every macrotile, and the global list. Each context needs a separate state page table.	Section 5.5.1.56
630h	EUR_CR_DPM_STATE_CONTEXT_ID		Section 5.5.1.57
634h	EUR_CR_DPM_CONTROL_TABLE_BASE	Effective immediately, this register defines the base address of the control table when it is read and written to/from memory. The control table itself contains the current offset into the page, and whether a page has been allocated, for each macrotile. Each context needs a separate state page table.	Section 5.5.1.58
638h	EUR_CR_DPM_START_OF_CONTEXT_PAGES_ALLOCATED		Section 5.5.1.59

5.5.1.8 EUR_CR_ISP_IPFMISC Register (offset = 414h)

Global control register for the ISP parameter fetch.

EUR_CR_ISP_IPFMISC is shown in Figure 5-8 and described in Table 5-9.

Figure 5-8. EUR_CR_ISP_IPFMISC Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-9. EUR_CR_ISP_IPFMISC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	Reserved	R/W	00h	
25-24	TTE_SCALE	R/W	0h	Scale factor for ISP parameter fetch to BIF TTE.
23-20	Reserved	R/W	0h	
19-16	UPASSSTART	R/W	0h	Initial upass_ctrl value, loaded at the start of each tile, for user pass spawning in the ISP.
15-9	Reserved	R/W	00h	
8	PROCESSEMPTY	R/W	0h	If this bit is set, all empty regions encountered will be processed by the 3D core ie the hardware background object being rendered in each empty tile. NOTE that this bit does not affect a "Fast Scale Render" i.e. empty regions are always processed when performing a "Fast Scale Render".
7-6	Reserved	R/W	0h	
5-0	VALIDID	R/W	00h	6 bit field specify the minimum object ID required for opaque and translucent objects to be rendered.

5.5.1.15 EUR_CR_ISP_BREAK Register (offset = 430h)

Object breakpoints can be inserted by the driver to interrupt a render part way and then resume the render from the point of interrupt at a later time, this register controls what happens when a breakpoint has been encountered.

EUR_CR_ISP_BREAK is shown in Figure 5-15 and described in Table 5-16.

Figure 5-15. EUR_CR_ISP_BREAK Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-16. EUR_CR_ISP_BREAK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	Reserved	W	0000000h	
4	RESUME	W	0h	Resumes the current render after a breakpoint object is encountered in the internal parameter stream
3-1	Reserved	W	0h	
0	HALT	W	0h	Terminates the current render after a breakpoint object is encountered in the internal parameter stream

DRAFT ONLY

5.5.1.20 EUR_CR_ISP_ZLSCTL Register (offset = 480h)

Image Synthesis Processor Z Load/Store and format global control register

EUR_CR_ISP_ZLSCTL is shown in Figure 5-20 and described in Table 5-21.

Figure 5-20. EUR_CR_ISP_ZLSCTL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-21. EUR_CR_ISP_ZLSCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	Reserved	R/W	000h	
22	STOREMASK	R/W	0h	This bit modifies the behaviour when ISP_ZLSCTL:[ZSTOREFORMAT] = 0x0. 0 - Binary 0 is stored in place of the current rendered mask plane. All stored Z values will appear in memory as positive IEEE floats; 1 - The mask plane is stored per pixel location a rendered to the on-chip tile buffer and occupies the MSB (sign bit) of all IEEE float dwords
21	LOADMASK	R/W	0h	This bit modifies the behaviour when ISP_ZLSCTL:[ZLOADFORMAT] = 0x0. 0 - The entire tile will be loaded with the mask plane value as determined by ISP_BGOBJ:[MASK]; 1 - The mask plane is loaded exactly as it appears in memory with the mask plane bit in the MSB (sign bit) of each loaded IEEE float formatted dword
20	ZONLYRENDER	R/W	0h	When set, only the Z buffer is rendered. Opaque and translucent objects are stencil and depth tested as usual but no pixel spans are emitted to the PDS Pixel presenter. Pixels within punch through and depth feedback objects are emitted on their first pass as a result of passing the up-front depth test by default. However, on their feedback depth test, these pixels will not be output regardless of the depth test result. The intention is to calculate a scene Z buffer without doing any further rendering.
19-18	ZSTOREFORMAT	R/W	0h	Selects the format depth, stencil and viewport is stored in: 0x0 32 bit IEEE SP Float; 0x1 24 bit Integer + 8-bit Stencil; 0x2 Two 16 bit Integers (Packed format); 0x3 32-bit IEEE Float 8-bit Stencil 1-bit Viewport Compressed, addressed using DPM
17-16	ZLOADFORMAT	R/W	0h	Selects the format depth, stencil and viewport is stored in: 0x0 32 bit IEEE SP Float; 0x1 24 bit Integer + 8-bit Stencil; 0x2 Two 16 bit Integers (Packed format); 0x3 32-bit IEEE Float 8-bit Stencil 1-bit Viewport Compressed, addressed using DPM
15-8	ZLSEXTENT	R/W	00h	Display width in tiles (16 pixels) minus one: 0x00 1 tile (16 pixels) 0x01 2 tiles (32 pixels) .. 0xFF 256 tiles (4096 pixels)
7	SSTOREEN	R/W	0h	When set to 1, if the ZSTORE bit in the region header is also set then the stencil buffer is stored to memory after each tile is processed
6	FORCEZSTORE	R/W	0h	If set to 1 the depth/stencil buffer is always stored at the end of each tile irrespective of the region header ZSTORE bit.
5	FORCEZLOAD	R/W	0h	If set to 1 the depth/stencil buffer is always loaded at the start of each tile irrespective of the region header ZLOAD bit.
4	ZSTOREEN	R/W	0h	When set to 1, if the ZSTORE bit in the region header is also set then the depth buffer is stored to memory after each tile is processed
3	STORETILED	R/W	0h	When set to 1 depth and stencil data is written out in "Tiled" order. (Note: Data can not be written as tiled, if the ZSTOREFORMAT = 0x3. In this case STORETILED should be set to 0)
2	ZLOADEN	R/W	0h	When set to 1, if the ZLOAD bit in the region header is also set then the depth buffer is read from memory prior to tile processing
1	SLOADEN	R/W	0h	When set to 1, if the ZLOAD bit in the region header is also set then the stencil buffer is read from memory prior to tile processing
0	LOADTILED	R/W	0h	When set to 1 depth, stencil data is loaded in "Tiled" order (Note: Data can not be read as tiled, if the ZSTOREFORMAT = 0x3. In this case LOADTILED should be set to 0)

5.5.1.36 EUR_CR_ISP_BGOBJTAG Register (offset = 4C4h)

The ISP operates by comparing depth values of incoming objects with the results of previous depth compares, in order to make sure there are no unitialised values at the start of the tile or to cover pixels where there are no objects in the scene a default background object is configured under register control. This register provides TSP and Vertex information for this background object.

EUR_CR_ISP_BGOBJTAG is shown in Figure 5-36 and described in Table 5-37.

Figure 5-36. EUR_CR_ISP_BGOBJTAG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-37. EUR_CR_ISP_BGOBJTAG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29-24	TSPDATASIZE	R/W	00h	Hardware background object TSP data size in dwords
23-22	Reserved	R/W	0h	
21-0	VERTEXPTR	R/W	000000h	Bits 25:4 of the hardware background object vertex pointer (64MB range on 16 byte boundaries)

5.5.1.37 EUR_CR_ISP_MULTISAMPLECTL Register (offset = 4C8h)

This applies when anti-aliasing is enabled. This is used by the ISP to adjust the sample positions.

EUR_CR_ISP_MULTISAMPLECTL is shown in Figure 5-37 and described in Table 5-38.

Figure 5-37. EUR_CR_ISP_MULTISAMPLECTL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-38. EUR_CR_ISP_MULTISAMPLECTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	MSAA_Y3	R/W	0h	Unsigned sub-pixel offset for the 4th multisample Y position
27-24	MSAA_X3	R/W	0h	Unsigned sub-pixel offset for the 4th multisample X position
23-20	MSAA_Y2	R/W	0h	Unsigned sub-pixel offset for the 3rd multisample Y position
19-16	MSAA_X2	R/W	0h	Unsigned sub-pixel offset for the 3rd multisample X position
15-12	MSAA_Y1	R/W	0h	Unsigned sub-pixel offset for the 2nd multisample Y position
11-8	MSAA_X1	R/W	0h	Unsigned sub-pixel offset for the 2nd multisample X position
7-4	MSAA_Y0	R/W	0h	Unsigned sub-pixel offset for the 1st multisample Y position
3-0	MSAA_X0	R/W	0h	Unsigned sub-pixel offset for the 1st multisample X position

5.5.1.50 EUR_CR_DPM_PDS_PAGE_THRESHOLD Register (offset = 614h)

This is the threshold in 4KB pages at which the hardware will stop double buffering the internal vertex processing buffers (and drop to single buffered mode). This is required in order to guarantee that a 3D render can run when running in dynamic parameter management mode. It should be set to 0.25MB less (in pages 0x40) than the ZLS threshold (or 0 in very small memory systems).

EUR_CR_DPM_PDS_PAGE_THRESHOLD is shown in Figure 5-50 and described in Table 5-51.

Figure 5-50. EUR_CR_DPM_PDS_PAGE_THRESHOLD Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-51. EUR_CR_DPM_PDS_PAGE_THRESHOLD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	Reserved	R/W	00000h	
13-0	VALUE	R/W	2000h	Page Threshold at which vertex buffers stop being double buffered

5.5.1.63 EUR_CR_DPM_DALLOC Register (offset = 644h)

A write to this register invalidates the current contents and causes a new de-allocation cycle

EUR_CR_DPM_DALLOC is shown in Figure 5-63 and described in Table 5-64.

Figure 5-63. EUR_CR_DPM_DALLOC Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-64. EUR_CR_DPM_DALLOC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	Reserved	R/W	0000h	
16	PAGE_FREE	R/W	0h	A read indicates whether the page has been freed
15-14	Reserved	R/W	0h	
13-0	PAGE	R/W	FFFFh	The page to be de-allocated by the hardware

DRAFT ONLY

5.5.1.64 EUR_CR_DPM_TA_ALLOC Register (offset = 648h)

EUR_CR_DPM_TA_ALLOC is shown in Figure 5-64 and described in Table 5-65.

Figure 5-64. EUR_CR_DPM_TA_ALLOC Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-65. EUR_CR_DPM_TA_ALLOC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29-16	FREE_LIST_PREVIOUS	R/W	0000h	Effective on Load TA Page Table Context: TA Alloc Free List Previous Page. The DPM maintains the previous and current free list pointers. On a context load this value must be loaded in. For the initial case it should be set to the penultimate page after initialisation (normally TAIL - 1).
15-0	Reserved	R/W	0000h	

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.65 EUR_CR_DPM_3D Register (offset = 64Ch)

EUR_CR_DPM_3D is shown in Figure 5-65 and described in Table 5-66.

Figure 5-65. EUR_CR_DPM_3D Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-66. EUR_CR_DPM_3D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29-16	FREE_LIST_PREVIOUS	R/W	0000h	Effective on Load 3D Page Table Context: 3D Free List Previous Page. The DPM maintains the previous and current free list pointers. On a context load this value must be loaded in. For the initial case it should be set to the penultimate page after initialisation (normally TAIL - 1).
15-0	Reserved	R/W	0000h	

DRAFT ONLY

5.5.1.66 EUR_CR_DPM_PARTIAL_RENDER Register (offset = 658h)

EUR_CR_DPM_PARTIAL_RENDER is shown in Figure 5-66 and described in Table 5-67.

Figure 5-66. EUR_CR_DPM_PARTIAL_RENDER Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-67. EUR_CR_DPM_PARTIAL_RENDER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R/W	00000000h	
0	ENABLE	R/W	0h	Once The TA DPM has run out of memory, and the driver has scheduled an abort, there must be a partial render performed on the context in order to free memory. This bit is set before the partial render is started.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.67 EUR_CR_DPM_LSS_PARTIAL_CONTEXT Register (offset = 65Ch)

EUR_CR_DPM_LSS_PARTIAL_CONTEXT is shown in Figure 5-67 and described in Table 5-68.

Figure 5-67. EUR_CR_DPM_LSS_PARTIAL_CONTEXT Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-68. EUR_CR_DPM_LSS_PARTIAL_CONTEXT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R/W	00000000h	
0	OPERATION	R/W	0h	When set indicates that on a Context state table load, reset or store only the best macro tile, rather than the full scene.

DRAFT ONLY

5.5.1.68 EUR_CR_DPM_START_OF_3D_CONTEXT_PAGES_ALLOCATED Register (offset = 660h)

EUR_CR_DPM_START_OF_3D_CONTEXT_PAGES_ALLOCATED is shown in Figure 5-68 and described in Table 5-69.

Figure 5-68. EUR_CR_DPM_START_OF_3D_CONTEXT_PAGES_ALLOCATED Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-69. EUR_CR_DPM_START_OF_3D_CONTEXT_PAGES_ALLOCATED Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29-16	GLOBAL	R/W	0000h	Effective on the loading of the 3D Page Table Context, this register defines the number of the pages which are currently allocated to the context global list. The value for this register is read from the matching status register, on a context store, and loaded on a context load.
15-14	Reserved	R/W	0h	
13-0	LOCAL	R/W	0000h	Effective on the loading of the 3D Page Table Context, this register defines the number of the pages which are currently allocated to the context. The value for this register is read from the matching status register, on a context store, and loaded on a context load.

5.5.1.69 EUR_CR_DPM_TASK_3D_FREE Register (offset = 680h)

EUR_CR_DPM_TASK_3D_FREE is shown in Figure 5-69 and described in Table 5-70.

Figure 5-69. EUR_CR_DPM_TASK_3D_FREE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-70. EUR_CR_DPM_TASK_3D_FREE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	W	00000000h	
0	LOAD	W	0h	Causes the 3D free list context to be loaded from the relevant configuration registers

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.70 EUR_CR_DPM_TASK_TA_FREE Register (offset = 684h)

EUR_CR_DPM_TASK_TA_FREE is shown in Figure 5-70 and described in Table 5-71.

Figure 5-70. EUR_CR_DPM_TASK_TA_FREE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-71. EUR_CR_DPM_TASK_TA_FREE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	W	00000000h	
0	LOAD	W	0h	Causes the TA free list context to be loaded from the relevant configuration registers

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.71 EUR_CR_DPM_TASK_STATE Register (offset = 694h)

This register controls the DPM module task state for page tables. The normal order of operation is Store context, Clear context, Load new context.

EUR_CR_DPM_TASK_STATE is shown in Figure 5-71 and described in Table 5-72.

Figure 5-71. EUR_CR_DPM_TASK_STATE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-72. EUR_CR_DPM_TASK_STATE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	W	00000000h	
2	LOAD	W	0h	Causes the state for the DPM page table to be read from memory. Only the selected context ID is loaded.
1	CLEAR	W	0h	Causes the state for the DPM page table to be cleared. Only the selected context ID is cleared.
0	STORE	W	0h	Causes the state for the DPM page table (non-destructive - the state is not cleared as it is written) to be written to memory. Only the selected context ID is written out.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.72 EUR_CR_DPM_TASK_CONTROL Register (offset = 698h)

This register controls the DPM module task state for control page tables. The normal order of operation is Store context, Clear context, Load new context.

EUR_CR_DPM_TASK_CONTROL is shown in Figure 5-72 and described in Table 5-73.

Figure 5-72. EUR_CR_DPM_TASK_CONTROL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-73. EUR_CR_DPM_TASK_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	W	00000000h	
2	LOAD	W	0h	Causes the state for the control page table to be read from memory.
1	CLEAR	W	0h	Causes the state for the control page table to be cleared.
0	STORE	W	0h	Causes the state for the control table (non-destructive - the control is not cleared as it is written) to be written to memory.

DRAFT ONLY

5.5.1.73 EUR_CR_DPM_OUTOFMEM Register (offset = 69Ch)

EUR_CR_DPM_OUTOFMEM is shown in Figure 5-73 and described in Table 5-74.

Figure 5-73. EUR_CR_DPM_OUTOFMEM Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-74. EUR_CR_DPM_OUTOFMEM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	W	00000000h	
2	ABORTALL	W	0h	Causes the hardware to initiate the abort cycle, resulting in an abort complete, and requiring a subsequent full render, in the order of busiest to least busy macro tile. The region headers need to be re-ordered by the driver to guarantee this condition
1	ABORT	W	0h	Causes the hardware to initiate the abort cycle, resulting in an abort complete, and requiring a subsequent partial render
0	RESTART	W	0h	Causes the parameter management to resume trying to allocate pages

DRAFT ONLY

5.5.1.76 EUR_CR_DPM_TA_EVM Register (offset = 6A8h)

EUR_CR_DPM_TA_EVM is shown in Figure 5-76 and described in Table 5-77.

Figure 5-76. EUR_CR_DPM_TA_EVM Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-77. EUR_CR_DPM_TA_EVM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	W	00000000h	
0	INIT	W	0h	Initialise the TA linked list (between start and end only), to an area of linear memory

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.77 EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS1 Register (offset = 700h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS1 is shown in Figure 5-77 and described in Table 5-78.

Figure 5-77. EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-78. EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R	0h	
29-16	TAIL	R	0000h	The current tail of the free list for the TA allocation context
15-14	Reserved	R	0h	
13-0	HEAD	R	0000h	The current head of the free list for the TA allocation context

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.78 EUR_CR_DPM_3D_FREE_LIST_STATUS1 Register (offset = 70Ch)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_3D_FREE_LIST_STATUS1 is shown in Figure 5-78 and described in Table 5-79.

Figure 5-78. EUR_CR_DPM_3D_FREE_LIST_STATUS1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-79. EUR_CR_DPM_3D_FREE_LIST_STATUS1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R	0h	
29-16	TAIL	R	0000h	The current tail of the free list for the 3D context
15-14	Reserved	R	0h	
13-0	HEAD	R	0000h	The current head of the free list for the 3D context

DRAFT ONLY

5.5.1.79 EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS2 Register (offset = 710h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS2 is shown in Figure 5-79 and described in Table 5-80.

Figure 5-79. EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-80. EUR_CR_DPM_TA_ALLOC_FREE_LIST_STATUS2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	Reserved	R	00000h	
13-0	PREVIOUS	R	0000h	The element before the tail of the free list for the TA allocation context

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.80 EUR_CR_DPM_3D_FREE_LIST_STATUS2 Register (offset = 71Ch)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_3D_FREE_LIST_STATUS2 is shown in Figure 5-80 and described in Table 5-81.

Figure 5-80. EUR_CR_DPM_3D_FREE_LIST_STATUS2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-81. EUR_CR_DPM_3D_FREE_LIST_STATUS2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	Reserved	R	00000h	
13-0	PREVIOUS	R	0000h	The element before the tail of the free list for the 3D context

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.81 EUR_CR_DPM_ABORT_STATUS_MTILE Register (offset = 720h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_ABORT_STATUS_MTILE is shown in Figure 5-81 and described in Table 5-82.

Figure 5-81. EUR_CR_DPM_ABORT_STATUS_MTILE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-82. EUR_CR_DPM_ABORT_STATUS_MTILE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0000000h	
4	GLOBAL	R	0h	Indicates that the whole scene must be aborted
3-0	INDEX	R	0h	The macro tile which will be aborted by the hardware

DRAFT ONLY

5.5.1.82 EUR_CR_DPM_PAGE_STATUS Register (offset = 724h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_PAGE_STATUS is shown in Figure 5-82 and described in Table 5-83.

Figure 5-82. EUR_CR_DPM_PAGE_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-83. EUR_CR_DPM_PAGE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R	0h	
29-16	TA	R	0000h	The number of pages allocated by the hardware, for the TA context
15-14	Reserved	R	0h	
13-0	TOTAL	R	0000h	The total number of pages allocated by the hardware, across all contexts

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.83 EUR_CR_DPM_PAGE Register (offset = 728h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_PAGE is shown in Figure 5-83 and described in Table 5-84.

Figure 5-83. EUR_CR_DPM_PAGE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-84. EUR_CR_DPM_PAGE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	Reserved	R	00000h	
13-0	STATUS_3D	R	0000h	The number of pages allocated by the hardware, for the 3D context

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.84 EUR_CR_DPM_GLOBAL_PAGE_STATUS Register (offset = 72Ch)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_GLOBAL_PAGE_STATUS is shown in Figure 5-84 and described in Table 5-85.

Figure 5-84. EUR_CR_DPM_GLOBAL_PAGE_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-85. EUR_CR_DPM_GLOBAL_PAGE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R	0h	
29-16	TA	R	0000h	The number of global pages allocated by the hardware, for the TA context
15-14	Reserved	R	0h	
13-0	TOTAL	R	0000h	The total number of global pages allocated by the hardware, across all contexts

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.85 EUR_CR_DPM_GLOBAL_PAGE Register (offset = 730h)

This status register is read for a context switch, and reprogrammed on a context load.

EUR_CR_DPM_GLOBAL_PAGE is shown in Figure 5-85 and described in Table 5-86.

Figure 5-85. EUR_CR_DPM_GLOBAL_PAGE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-86. EUR_CR_DPM_GLOBAL_PAGE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	Reserved	R	00000h	
13-0	STATUS_3D	R	0000h	The total number of global pages allocated by the hardware, across the 3D contexts

DRAFT ONLY

EUR_CR_DPM_REQUESTING is shown in Figure 5-86 and described in Table 5-87.

Figure 5-86. EUR_CR_DPM_REQUESTING Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-87. EUR_CR_DPM_REQUESTING Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	00000000h	
1-0	SOURCE	R	0h	The device that is requesting memory; Bit 0 is the TA (Control Stream Request), Bit 1 is the TA (Vertex Data Stream Request)

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.87 EUR_CR_DPM_RNG_HDR_PARSER Register (offset = 738h)

EUR_CR_DPM_RNG_HDR_PARSER is shown in Figure 5-87 and described in Table 5-88.

Figure 5-87. EUR_CR_DPM_RNG_HDR_PARSER Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-88. EUR_CR_DPM_RNG_HDR_PARSER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	IDLE	R	1h	The DPM Region Header IDLE indication, 1 = idle, 0 = busy

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.88 EUR_CR_CORE_REVISION Register (offset = 14h)

Core Revision Register identifies the specific core revision. This is updated to reflect the formal release status of the core.

EUR_CR_CORE_REVISION is shown in Figure 5-88 and described in Table 5-89.

Figure 5-88. EUR_CR_CORE_REVISION Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-89. EUR_CR_CORE_REVISION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	DESIGNER	R	00h	Designer Field
23-16	MAJOR	R	01h	Major Revision
15-8	MINOR	R	02h	Minor Revision
7-0	MAINTENANCE	R	0Fh	Maintenance Revision

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.89 EUR_CR_TSP_CONFIG Register (offset = 800h)

EUR_CR_TSP_CONFIG is shown in Figure 5-89 and described in Table 5-90.

Figure 5-89. EUR_CR_TSP_CONFIG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-90. EUR_CR_TSP_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	R/W	00000000h	
2	CEMEDGE_DONTFILTER	R/W	0h	Disable filtering over edges/corners for CEM
1	CEMGRAD_DONTNEGATE	R/W	0h	Disable negation for user supplied gradients for cem swap i.e. will only swap dudx etc not negate
0	Reserved	R/W	0h	

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.90 EUR_CR_CACHE_CTRL Register (offset = 804h)

Unified Cache global control register

EUR_CR_CACHE_CTRL is shown in Figure 5-90 and described in Table 5-91.

Figure 5-90. EUR_CR_CACHE_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-91. EUR_CR_CACHE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29	L0P0OFF	R/W	0h	Cache L0 Pipe1 Bypass
28	INVALIDATE	R/W	0h	Cache Invalidate - To invalidate the cache, ie remove all contents from the cache, then setting this bit to 1 will start an invalidation cycle within the cache. Immediately the cache will not except anymore read request until the invalidation cycle completes. All requests pending in the cache (L0/L1/L2) will be completed before the cache completes its invalidation cycle. On completion of the invalidation cycle an interrupt will occur, if enabled, and the MADD_CACHE_INVALCOMP bit will be set and the cache will return to its normal operation
27	Reserved	R/W	0h	
26	L1P1OFF	R/W	0h	Cache Off L1 Pipe1 - When set to 1 turns off the L1 cache associated with Pipe 1. Read request to the L1 cache will be forwarded directly to the L2 cache. The cache must be invalidated after the bit is set to 0 (Cache Level On)
25	L1P0OFF	R/W	0h	Cache Off L1 Pipe0 - When set to 1 turns off the L1 cache associated with Pipe 0. Read request to the L1 cache will be forwarded directly to the L2 cache. The cache must be invalidated after the bit is set to 0 (Cache Level On)
24-16	Reserved	R/W	000h	
15-12	PARTDM3	R/W	0h	Cache Partition Mask for DM3 - defines which cache lines are used for Data Master type 3. Each bit represents one cache line, where there are 4 cache lines in the cache. Each cache line contains 8 possible address tags which are compared against the incoming address to determine if the data requested is in the cache or not. If all bits are set then there are 4 x 8 possible address tags i.e. DM3 read request will try and match against all the cache ram contents. Setting a bit to 0, will exclude that cache line from being compared against the incoming request address
11-8	PARTDM2	R/W	0h	Cache Partition Mask for DM2 - Refer to PARTDM3, but with respect to DM2
7-4	PARTDM1	R/W	0h	Cache Partition Mask for DM1 - Refer to PARTDM3, but with respect to DM1
3-0	PARTDM0	R/W	0h	Cache Partition Mask for DM0 - Refer to PARTDM3, but with respect to DM0

5.5.1.114 EUR_CR_EVENT_PDS_ENABLE Register (offset = A58h)

Enables general event bits into the PDS event data master for processing by the PDS Micro Controller

EUR_CR_EVENT_PDS_ENABLE is shown in Figure 5-114 and described in Table 5-115.

Figure 5-114. EUR_CR_EVENT_PDS_ENABLE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-115. EUR_CR_EVENT_PDS_ENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29	TIMER	R/W	0h	PDS_Enable: The PDS Event timer interrupt (signalled on timer traversing through 0).
28	TA_DPM_FAULT	R/W	0h	PDS_Enable: The TA Object Passing System has got out of sync, a Terminate Control Word DPM read was met by StartofBlock data
27	Reserved	R/W	0h	
26	MADD_CACHE_INVALCOMPLETE	R/W	0h	PDS_Enable: Invalidate of Madd L0, L1, L2 Cache Complete
25	DPM_OUT_OF_MEMORY_ZLS	R/W	0h	PDS_Enable: Memory Allocation Failed for ZLS
24	DPM_TA_MEM_FREE	R/W	0h	PDS_Enable: All memory associated with TA context has been freed
23	ISP_END_PASS	R/W	0h	PDS_Enable: ISP End pass
22	DPM_INITEND	R/W	0h	PDS_Enable: DPM Initialisation Complete
21	OTPM_LOADED	R/W	0h	PDS_Enable: The OTPM has loaded its state
20	OTPM_INV	R/W	0h	PDS_Enable: The OTPM has invalidated its contents
19	OTPM_FLUSHED	R/W	0h	PDS_Enable: The OTPM has flushed its state
18	PIXELBE_END_RENDER	R/W	0h	PDS_Enable: End of Scene
17	ISP_HALT	R/W	0h	PDS_Enable: ISP Halt breakpoint triggered
16	ISP_VISIBILITY_FAIL	R/W	0h	PDS_Enable: Visibility Test Fail
15	BREAKPOINT	R/W	0h	PDS_Enable: ISP Breakpoint
14	SW_EVENT	R/W	0h	PDS_Enable: Software triggered event
13	TA_FINISHED	R/W	0h	PDS_Enable: TA complete, (Scene Terminated)
12	TA_TERMINATE	R/W	0h	PDS_Enable: The TA terminate complete (issue as part of complex scene) (MacroTile aborted)
11	TPC_CLEAR	R/W	0h	PDS_Enable: The TPC has reset its state
10	TPC_FLUSH	R/W	0h	PDS_Enable: The TPC has stored its state
9	DPM_CONTROL_CLEAR	R/W	0h	PDS_Enable: The reset of the DPM control context has been completed
8	DPM_CONTROL_LOAD	R/W	0h	PDS_Enable: The load of the DPM control context has been completed
7	DPM_CONTROL_STORE	R/W	0h	PDS_Enable: The store of the DPM control context has been completed
6	DPM_STATE_CLEAR	R/W	0h	PDS_Enable: The reset of the DPM state context has been completed
5	DPM_STATE_LOAD	R/W	0h	PDS_Enable: The load of the DPM state context has been completed
4	DPM_STATE_STORE	R/W	0h	PDS_Enable: The store of the DPM state context has been completed
3	DPM_REACHED_MEM_THRESH	R/W	0h	PDS_Enable: DPM Memory allocation has reached the preset memory threshold for total memory allocation
2	DPM_OUT_OF_MEMORY_GBL	R/W	0h	PDS_Enable: DPM Memory allocation failed for the global list
1	DPM_OUT_OF_MEMORY_MT	R/W	0h	PDS_Enable: DPM Memory allocation failed for a macro tile

5.5.1.120 EUR_CR_EVENT_OTHER_PDS_INFO Register (offset = A70h)

EUR_CR_EVENT_OTHER_PDS_INFO is shown in Figure 5-120 and described in Table 5-121.

Figure 5-120. EUR_CR_EVENT_OTHER_PDS_INFO Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-121. EUR_CR_EVENT_OTHER_PDS_INFO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	Reserved	R/W	00h	
25	USESECEXEC	R/W	0h	Secondary tasks should execute on the USSE
24-22	OBUFFER_REQD	R/W	0h	The number of output buffers to be allocated
21-13	ATTRIBUTE_SIZE	R/W	000h	The attribute size in 128 bit words
12-11	DM	R/W	0h	Selects the Data Master 0 - Vertex: Vertex 1 - Pixel: Pixel 2 - Reserved_2: Reserved 3 - Event: Event
10	PNS	R/W	0h	Allocate primary not secondary memory
9-8	USE_PIPELINE	R/W	0h	Selects the USSE pipeline allocated to the data master 0 - Data: Data master selects the USSE pipeline 1 - PIPE0: Pipe 0 2 - PIPE1: Pipe 1 3 - Pipes: Pipes 0 and 1
7-1	ODS	R/W	00h	The output data stride in 128 bit words
0	SD	R/W	0h	Sequential Dependency bit. All end of tile tasks should set this bit, in order to ensure that preceding pixel tasks complete before the tile is emitted.

5.5.1.121 EUR_CR_DMS_CTRL Register (offset = A74h)

Control register used to disable individual data masters - '1' - disable data master, '0' - enable data master

EUR_CR_DMS_CTRL is shown in Figure 5-121 and described in Table 5-122.

Figure 5-121. EUR_CR_DMS_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-122. EUR_CR_DMS_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R/W	0h	
27-25	MAX_NUM_VERTEX_PARTITIONS	R/W	0h	The maximum number of partitions allowed on each USSE for vertex tasks
24-22	MAX_NUM_PIXEL_PARTITIONS	R/W	0h	The maximum number of partitions allowed on each USSE for pixel tasks
21-16	MAX_NUM_EDM_TASKS	R/W	00h	The maximum number of vertex tasks allowed on each USSE, range 0 to 32
15-10	MAX_NUM_VERTEX_TASKS	R/W	00h	The maximum number of vertex tasks allowed on each USSE, range 0 to 32
9-4	MAX_NUM_PIXEL_TASKS	R/W	00h	The maximum number of pixel tasks allowed on each USSE, range 0 to 32
3	DISABLE_DM_LOOPBACK	R/W	0h	Disable Loopback DM
2	DISABLE_DM_EVENT	R/W	0h	Disable Event DM
1	DISABLE_DM_PIXEL	R/W	0h	Disable Pixel DM
0	DISABLE_DM_VERTEX	R/W	0h	Disable Vertex DM

5.5.1.132 EUR_CR_EVENT_HOST_ENABLE2 Register (offset = 110h)

This register enables interrupts. Writing a '1' to a bit field enables the relevant Event. All the bit fields correspond exactly to those in the EUR_CR_EVENT_STATUS2 register. The MASTER_INTERRUPT bit is a global enable which overrides the Event enables, i.e. '1' - enable external interrupts, '0' - disable external interrupts.

EUR_CR_EVENT_HOST_ENABLE2 is shown in Figure 5-132 and described in Table 5-133.

Figure 5-132. EUR_CR_EVENT_HOST_ENABLE2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-133. EUR_CR_EVENT_HOST_ENABLE2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	Reserved	R/W	0000000h

5.5.1.142 EUR_CR_EVENT_TIMER Register (offset = ACCh)

The timer which runs at the core clock when enabled, decrementing from the loaded value. Wraps when it hits 0 back to the starting value. A transition through 0 creates an event, which can be enabled into either the PDS or the Host status register. The timer can also be read/written from within the PDS program.

EUR_CR_EVENT_TIMER is shown in Figure 5-142 and described in Table 5-143.

Figure 5-142. EUR_CR_EVENT_TIMER Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-143. EUR_CR_EVENT_TIMER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	Reserved	R/W	00h	
24	ENABLE	R/W	0h	A value of '1' enables the timer, 0 disables the counter (halts without initialisation to 0).
23-0	VALUE	R/W	000000h	The Starting value for the timer (loaded on write from wither PDS or host).

5.5.1.152 EUR_CR_EVENT_STATUS2 Register (offset = 118h)

There are 2 sources of external interrupts in the PowerVR SGX core: General system events and PDS cache invalidation events. The event status2 register indicates the source of any general event interrupt generated by PowerVR SGX. These events only result in an external interrupt if the relevant bit in the EUR_CR_EVENT_HOST_ENABLE register is set. Note1: This register must be combined with the EUR_CR_PDS_CACHE_STATUS register information to determine what has caused the external interrupt. Note2: The host can write to this register in which case any bits written as a '1' are ORed into the register i.e. the host can cause the core to generate an interrupt. (This is typically for debug purposes only)

EUR_CR_EVENT_STATUS2 is shown in Figure 5-152 and described in Table 5-153.

5.5.1.158 EUR_CR_LOOPBACK Register (offset = B04h)

This USE can issue loopback tasks through the PDS back to itself. This bit indicates the status of this interface. A value of 1 should that there are no pending loopback requests (for any USE pipeline), A value of 0 indicates that a loop task is pending, and that further loopback events may cause the USE pipeline to wait until new resource becomes available. Issuing loopback events when tasks are already pending is not recommended, as this may result in system lockups.

EUR_CR_LOOPBACK is shown in Figure 5-158 and described in Table 5-159.

Figure 5-158. EUR_CR_LOOPBACK Register

5.5.1.170 EUR_CR_EVENT_STATUS Register (offset = 12Ch)

There are 2 sources of external interrupts in the PowerVR SGX core: General system events and PDS cache invalidation events. The event status register indicates the source of any general event interrupt generated by PowerVR SGX. These events only result in an external interrupt if the relevant bit in the EUR_CR_EVENT_HOST_ENABLE register is set. Note1: This register must be combined with the EUR_CR_PDS_CACHE_STATUS register information to determine what has caused the external interrupt. Note2: The host can write to this register in which case any bits written as a '1' are ORed into the register i.e. the host can cause the core to generate an interrupt. (This is typically for debug purposes only)

EUR_CR_EVENT_STATUS is shown in Figure 5-170 and described in Table 5-171.

Figure 5-170. EUR_CR_EVENT_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-171. EUR_CR_EVENT_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MASTER_INTERRUPT	R/W	0h	Status: PowerVR SGX Master Interrupt Control
30	Reserved	R/W	0h	
29	TIMER	R/W	0h	Status: The PDS Event timer interrupt (signalled on timer traversing through 0).
28	TA_DPM_FAULT	R/W	0h	Status: The TA Object Passing System has got out of sync, a Terminate Control Word DPM read was met by StartofBlock data
27	Reserved	R/W	0h	
26	MADD_CACHE_INVALCOMPLETE	R/W	0h	Status: Invalidate of Madd L0, L1, L2 Cache Complete
25	DPM_OUT_OF_MEMORY_ZLS	R/W	0h	Status: Memory Allocation Failed for ZLS
24	DPM_TA_MEM_FREE	R/W	0h	Status: All memory associated with TA context has been freed
23	ISP_END_TILE	R/W	0h	Status: ISP End tile
22	DPM_INITEND	R/W	0h	Status: DPM Initialisation Complete
21	OTPM_LOADED	R/W	0h	Status: The OTPM has loaded its state
20	OTPM_INV	R/W	0h	Status: The OTPM has invalidated its contents
19	OTPM_FLUSHED	R/W	0h	Status: The OTPM has flushed its state
18	PIXELBE_END_RENDER	R/W	0h	Status: End of Scene
17	ISP_HALT	R/W	0h	Status: ISP Halt breakpoint triggered
16	ISP_VISIBILITY_FAIL	R/W	0h	Status: Visibility Test Fail
15	BREAKPOINT	R/W	0h	Status: ISP Breakpoint
14	SW_EVENT	R/W	0h	Status: Software triggered event
13	TA_FINISHED	R/W	0h	Status: TA complete - This is set and held high after the TE terminates scene, until TA is restarted
12	TA_TERMINATE	R/W	0h	Status: The TA terminate complete (issue as part of complex scene) - This is set and held high after the TE aborts a MacroTile after failed DPM allocation request, until TA is restarted
11	TPC_CLEAR	R/W	0h	Status: The TPC has reset its state
10	TPC_FLUSH	R/W	0h	Status: The TPC has stored its state
9	DPM_CONTROL_CLEAR	R/W	0h	Status: The reset of the DPM control context has been completed
8	DPM_CONTROL_LOAD	R/W	0h	Status: The load of the DPM control context has been completed
7	DPM_CONTROL_STORE	R/W	0h	Status: The store of the DPM control context has been completed
6	DPM_STATE_CLEAR	R/W	0h	Status: The reset of the DPM state context has been completed
5	DPM_STATE_LOAD	R/W	0h	Status: The load of the DPM state context has been completed
4	DPM_STATE_STORE	R/W	0h	Status: The store of the DPM state context has been completed

5.5.1.171 EUR_CR_EVENT_HOST_ENABLE Register (offset = 130h)

This register enables interrupts. Writing a '1' to a bit field enables the relevant Event. All the bit fields correspond exactly to those in the EUR_CR_EVENT_STATUS register. The MASTER_INTERRUPT bit is a global enable which overrides the Event enables, i.e. '1' - enable external interrupts, '0' - disable external interrupts.

EUR_CR_EVENT_HOST_ENABLE is shown in Figure 5-171 and described in Table 5-172.

Figure 5-171. EUR_CR_EVENT_HOST_ENABLE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-172. EUR_CR_EVENT_HOST_ENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MASTER_INTERRUPT	R/W	0h	Host_Enable: PowerVR SGX Master Interrupt Control
30	Reserved	R/W	0h	
29	TIMER	R/W	0h	Host_Enable: The PDS Event timer interrupt (signalled on timer traversing through 0).
28	TA_DPM_FAULT	R/W	0h	Host_Enable: The Tiling Co-Processor Object Passing System has got out of sync, a Terminate Control Word DPM read was met by StartofBlock data
27	Reserved	R/W	0h	
26	MADD_CACHE_INVALCOMPLETE	R/W	0h	Host_Enable: Invalidate of Madd L0, L1, L2 Cache Complete
25	DPM_OUT_OF_MEMORY_ZLS	R/W	0h	Host_Enable: Memory Allocation Failed for ZLS
24	DPM_TA_MEM_FREE	R/W	0h	Host_Enable: All memory associated with TA context has been freed
23	ISP_END_TILE	R/W	0h	Host_Enable: ISP End tile
22	DPM_INITEND	R/W	0h	Host_Enable: DPM Initialisation Complete
21	OTPM_LOADED	R/W	0h	Host_Enable: The OTPM has loaded its state
20	OTPM_INV	R/W	0h	Host_Enable: The OTPM has invalidated its contents
19	OTPM_FLUSHED	R/W	0h	Host_Enable: The OTPM has flushed its state
18	PIXELBE_END_RENDER	R/W	0h	Host_Enable: End of Scene
17	ISP_HALT	R/W	0h	Host_Enable: ISP Halt breakpoint triggered
16	ISP_VISIBILITY_FAIL	R/W	0h	Host_Enable: Visibility Test Fail
15	BREAKPOINT	R/W	0h	Host_Enable: ISP Breakpoint
14	SW_EVENT	R/W	0h	Host_Enable: Software triggered event
13	TA_FINISHED	R/W	0h	Host_Enable: Tiling Co-Processor complete, (Scene Terminated)
12	TA_TERMINATE	R/W	0h	Host_Enable: The Tiling Co-Processor terminate complete (issue as part of complex scene) (MacroTile Aborted)
11	TPC_CLEAR	R/W	0h	Host_Enable: The TPC has reset its state
10	TPC_FLUSH	R/W	0h	Host_Enable: The TPC has stored its state
9	DPM_CONTROL_CLEAR	R/W	0h	Host_Enable: The reset of the DPM control context has been completed
8	DPM_CONTROL_LOAD	R/W	0h	Host_Enable: The load of the DPM control context has been completed
7	DPM_CONTROL_STORE	R/W	0h	Host_Enable: The store of the DPM control context has been completed
6	DPM_STATE_CLEAR	R/W	0h	Host_Enable: The reset of the DPM state context has been completed
5	DPM_STATE_LOAD	R/W	0h	Host_Enable: The load of the DPM state context has been completed
4	DPM_STATE_STORE	R/W	0h	Host_Enable: The store of the DPM state context has been completed
3	DPM_REACHED_MEM_THRESH	R/W	0h	Host_Enable: DPM Memory allocation has reached the preset memory threshold for total memory allocation

5.5.1.172 EUR_CR_BIF_CTRL Register (offset = C00h)

EUR_CR_BIF_CTRL is shown in Figure 5-172 and described in Table 5-173.

Figure 5-172. EUR_CR_BIF_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-173. EUR_CR_BIF_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	Reserved	R/W	0000h	
15	MMU_BYPASS_USE	R/W	1h	Setting to '1' bypasses the MMU for this requestor
14	MMU_BYPASS_ISP	R/W	1h	Setting to '1' bypasses the MMU for this requestor
13	MMU_BYPASS_TSPP	R/W	1h	Setting to '1' bypasses the MMU for this requestor
12	MMU_BYPASS_PBE	R/W	1h	Setting to '1' bypasses the MMU for this requestor
11	Reserved	R/W	1h	
10	MMU_BYPASS_TE	R/W	1h	Setting to '1' bypasses the MMU for this requestor
9	MMU_BYPASS_VDM	R/W	1h	Setting to '1' bypasses the MMU for this requestor
8	MMU_BYPASS_CACHE	R/W	1h	Setting to '1' bypasses the MMU for this requestor
7-5	Reserved	R/W	0h	
4	CLEAR_FAULT	R/W	0h	Writing '1' clears the current fault in the EUR_CR_BIF_INT_STAT register
3	INVALDC	R/W	0h	Writing '1' causes flushing of directory cache (and all other caches and tlbs)
2	FLUSH	R/W	0h	Writing '1' causes flushing of address translation cache and all tlbs
1	PAUSE	R/W	0h	Writing '1' causes bif operation to pause
0	NOREORDER	R/W	0h	Writing '1' disables transaction re-ordering by signaling to the external SoC infrastructure to closely order the requests (Debug Only)

5.5.1.174 EUR_CR_EVENT_HOST_CLEAR Register (offset = 134h)

This register is used to clear event interrupts. Writing a '1' to a bit field clears the relevant Event. All the bit fields correspond exactly to those in the EUR_CR_EVENT_STATUS register.

EUR_CR_EVENT_HOST_CLEAR is shown in Figure 5-174 and described in Table 5-175.

Figure 5-174. EUR_CR_EVENT_HOST_CLEAR Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-175. EUR_CR_EVENT_HOST_CLEAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MASTER_INTERRUPT	R/W	0h	Host_Clear: PowerVR SGX Master Interrupt
30	Reserved	R/W	0h	
29	TIMER	R/W	0h	Host_Clear: The PDS Event timer interrupt (signalled on timer traversing through 0).
28	TA_DPM_FAULT	R/W	0h	Host_Clear: The TA Object Passing System has got out of sync, a Terminate Control Word DPM read was met by StartofBlock data
27	Reserved	R/W	0h	
26	MADD_CACHE_INVALCOMPLETE	R/W	0h	Host_Clear: Invalidate of Madd L1, L2 Cache Complete
25	DPM_OUT_OF_MEMORY_ZLS	R/W	0h	Host_Clear: Memory Allocation Failed for ZLS
24	DPM_TA_MEM_FREE	R/W	0h	Host_Clear: All memory associated with TA context has been freed
23	ISP_END_TILE	R/W	0h	Host_Clear: ISP End tile
22	DPM_INITEND	R/W	0h	Host_Clear: DPM Initialisation Complete
21	OTPM_LOADED	R/W	0h	Host_Clear: The OTPM has loaded its state
20	OTPM_INV	R/W	0h	Host_Clear: The OTPM has invalidated its contents
19	OTPM_FLUSHED	R/W	0h	Host_Clear: The OTPM has flushed its state
18	PIXELBE_END_RENDER	R/W	0h	Host_Clear: End of Scene
17	ISP_HALT	R/W	0h	Host_Clear: ISP Halt breakpoint triggered
16	ISP_VISIBILITY_FAIL	R/W	0h	Host_Clear: Visibility Test Fail
15	BREAKPOINT	R/W	0h	Host_Clear: ISP Breakpoint
14	SW_EVENT	R/W	0h	Host_Clear: Software triggered event
13	TA_FINISHED	R/W	0h	Host_Clear: Tiling Co-Processor complete (Scene Terminated)
12	TA_TERMINATE	R/W	0h	Host_Clear: The Tiling Co-Processor terminate complete (issue as part of complex scene) (MacroTile aborted)
11	TPC_CLEAR	R/W	0h	Host_Clear: The TPC has reset its state
10	TPC_FLUSH	R/W	0h	Host_Clear: The TPC has stored its state
9	DPM_CONTROL_CLEAR	R/W	0h	Host_Clear: The reset of the DPM control context has been completed
8	DPM_CONTROL_LOAD	R/W	0h	Host_Clear: The load of the DPM control context has been completed
7	DPM_CONTROL_STORE	R/W	0h	Host_Clear: The store of the DPM control context has been completed
6	DPM_STATE_CLEAR	R/W	0h	Host_Clear: The reset of the DPM state context has been completed
5	DPM_STATE_LOAD	R/W	0h	Host_Clear: The load of the DPM state context has been completed
4	DPM_STATE_STORE	R/W	0h	Host_Clear: The store of the DPM state context has been completed
3	DPM_REACHED_MEM_THRESH	R/W	0h	Host_Clear: DPM Memory allocation has reached the preset memory threshold for total memory allocation
2	DPM_OUT_OF_MEMORY_GBL	R/W	0h	Host_Clear: DPM Memory allocation failed for the global list
1	DPM_OUT_OF_MEMORY_MT	R/W	0h	Host_Clear: DPM Memory allocation failed for a macro tile
0	DPM_3D_MEM_FREE	R/W	0h	Host_Clear: DPM Memory allocation complete for the current render

5.5.1.176 EUR_CR_PDS_CACHE_STATUS Register (offset = 138h)

There are 2 sources of external interrupts in the PowerVR SGX core: General system events and PDS cache invalidation events. The PDS cache status register indicates the source of any PDS cache invalidation event interrupts generated by PowerVR SGX. These events only result in an external interrupt if the relevant bit in the EUR_CR_PDS_CACHE_HOST_ENABLE register is set. Note1: This register must be combined with the EUR_CR_EVENT_STATUS register information to determine what has caused the external interrupt. Note2: The host can write to this register in which case any bits written as a '1' are ORed into the register i.e. the host can cause the core to generate an interrupt. (This is typically for debug purposes only)

EUR_CR_PDS_CACHE_STATUS is shown in Figure 5-176 and described in Table 5-177.

Figure 5-176. EUR_CR_PDS_CACHE_STATUS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 5-177. EUR_CR_PDS_CACHE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	Reserved	R/W	000000h	
8	DSC1_INV3	R/W	0h	Status: Context ID 3 has been invalidated in PDS Data Store Cache 1

5.5.1.188 EUR_CR_TE_MTILE2 Register (offset = 20Ch)

The Tiling Co-Processor allocates memory in macrotiles, which is a group of individual tiles. The number of macrotiles is selectable between 4 and 16, the boundaries of the macrotiles in the Y axis are defined in this register.

EUR_CR_TE_MTILE2 is shown in Figure 5-188 and described in Table 5-189.

Figure 5-188. EUR_CR_TE_MTILE2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-189. EUR_CR_TE_MTILE2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	Reserved	R/W	0h	
29-22	Y1	R/W	00h	Y1 MacroTile boundary, top tile Y for second row of macrotiles (16MT mode)
21-20	Reserved	R/W	0h	
19-12	Y2	R/W	00h	Y2 MacroTile boundary, top tile Y for second(4MT)/third(16MT) row of macrotiles
11-8	Reserved	R/W	0h	
7-0	Y3	R/W	00h	Y1 MacroTile boundary, top tile Y for fourth row of macrotiles (16MT mode)

5.5.1.189 EUR_CR_TE_SCREEN Register (offset = 210h)

In order to perform the tiling operation and generate the display list the maximum screen size must be configured in terms of the number of tiles in X and Y axis.

EUR_CR_TE_SCREEN is shown in Figure 5-189 and described in Table 5-190.

Figure 5-189. EUR_CR_TE_SCREEN Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-190. EUR_CR_TE_SCREEN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	Reserved	R/W	000h	
19-12	YMAX	R/W	00h	Maximum Y tile address visible on screen
11-8	Reserved	R/W	0h	
7-0	XMAX	R/W	00h	Maximum X tile address visible on screen

DRAFT ONLY

5.5.1.190 EUR_CR_TE_MTILE Register (offset = 214h)

This register defines the number of individual tiles within the macrotiles. This is used in the process of memory allocation.

EUR_CR_TE_MTILE is shown in Figure 5-190 and described in Table 5-191.

Figure 5-190. EUR_CR_TE_MTILE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-191. EUR_CR_TE_MTILE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	Reserved	R/W	0000h	
17-0	STRIDE	R/W	00000h	Number of tiles in a Macrotile. Stride = (XTile * YTiles)

5.5.1.191 EUR_CR_TE_PSG Register (offset = 218h)

This register defines the global control for the Parameter Stream Generator within the Tiling Co-Processor. This module formats the display list generated by the Tiling Co-Processor.

EUR_CR_TE_PSG is shown in Figure 5-191 and described in Table 5-192.

Figure 5-191. EUR_CR_TE_PSG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-192. EUR_CR_TE_PSG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	Reserved	R/W	00h	
24	ENABLE_CONTEXT_STATE_RESTORE	R/W	0h	Enables sampling of Driver TE_STATE_ISP_STATE_ID register on context switch/restore when set, when reset current local value is preserved.
23	ZONLYRENDER	R/W	0h	Don't invalidate Tail Pointer Cache entries on a Terminate command. Only effective when COMPLETEONTERMINATE is 0x0 0 - Do: Do Invalidate 1 - Don: Don't Invalidate
22	COMPLETEONTERMINATE	R/W	0h	0x1 Write region headers, terminate streams and invalidate tail pointer cache entries on terminate. 0 - If: If ZONLYRENDER = 0x0 then force an Interrupt, however if ZONLYRENDER = 0x1 then write region headers and terminate streams.
21	ZLOADENABLE	R/W	0h	If 0x1 set the zload enable bit in the region headers. If 0x0 the region header zload bit is controlled by the hardware automatically. The bit is set if a partial render has been performed on that tile.
20	ZSTOREENABLE	R/W	0h	If 0x1 set the zstore enable bit in the region headers. If 0x0 the region header zstore bit is controlled by the hardware automatically. The bit is set if a partial render is about to be performed on that tile.
19	PADZEROS	R/W	0h	Pad empty doublewords in allocation with zeros after Stream Link/Terminate. The allocation block size is 16 DWords, so potentially inserts 13 extra DWords of zeros into a pointer block. Debug only. Makes examination of memory more readable on a per frame basis.
18	FORCENEWSTATE	R/W	0h	Always embed state information in control stream. Debug only.
17-0	Reserved	R/W	00000h	

DRAFT ONLY

5.5.1.192 EUR_CR_TE_PSGREGION_BASE Register (offset = 21Ch)

This register defines the base address in memory of the Region Header writes by the TA. Region headers are the first part of the display list and contain an entry per tile with information on global setup and a link address to parameters.

EUR_CR_TE_PSGREGION_BASE is shown in Figure 5-192 and described in Table 5-193.

Figure 5-192. EUR_CR_TE_PSGREGION_BASE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-193. EUR_CR_TE_PSGREGION_BASE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R/W	0h	
27-6	ADDR	R/W	000000h	256MB Addressable, 512-bit aligned Base Address for Region Header writes
5-0	Reserved	R/W	00h

5.5.1.193 EUR_CR_TE_TPC_BASE Register (offset = 220h)

This register defines the base address in memory of the Tail Pointer Cache. A tail pointer is the current last address written to for a tiles individual display list, an entry for active tiles is maintained as primitives are processed by the TA.

EUR_CR_TE_TPC_BASE is shown in Figure 5-193 and described in Table 5-194.

Figure 5-193. EUR_CR_TE_TPC_BASE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-194. EUR_CR_TE_TPC_BASE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	Reserved	R/W	0h	
27-6	ADDR	R/W	000000h	256MB Addressable, 512-bit aligned Base Address for Tail Pointer Cache. The tail pointer is the current last address written to for a control stream for a tile.
5-0	Reserved	R/W	00h	

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

5.5.1.194 EUR_CR_TE_TPCCONTROL Register (offset = 224h)

The Tail Pointer Cache is used to keep track of the last address written to for a particular tile, this is stored in a mixture of on chip cache and external memory. Under certain circumstances it is necessary to either reset the cache or flush the on chip cache contents such that they are visible in memory.

EUR_CR_TE_TPCCONTROL is shown in Figure 5-194 and described in Table 5-195.

Figure 5-194. EUR_CR_TE_TPCCONTROL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-195. EUR_CR_TE_TPCCONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CLEAR	W	0h	Reset contents of Tail Pointer Cache
30	FLUSH	W	0h	Flush contents of Tail Pointer Cache to Memory
29-0	Reserved	W	00000000h

5.5.1.216 EUR_CR_CLKGATECTLOVR Register (offset = 8h)

Core module clock gating override controls: allows clocks to be enabled temporarily for register writes by hosts.

EUR_CR_CLKGATECTLOVR is shown in Figure 5-216 and described in Table 5-217.

Figure 5-216. EUR_CR_CLKGATECTLOVR Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 5-217. EUR_CR_CLKGATECTLOVR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	Reserved	R/W	000h	
21-20	USE_CLKO	R/W	0h	Clock gating control override for the USSE 0 - Reserved_0: Reserved 1 - Enabled: Host enable clock to the USSE request 2 - Reserved_2: Reserved 3 - Disabled: Host disable clock to USSE request. USSE clock may be gated if not other outstanding host requests.
19-18	Reserved	R/W	0h	
17-16	DPM_CLKO	R/W	0h	Clock gating control override for the DPM 0 - Reserved_0: Reserved 1 - Enabled: Clock to the DPM is enabled 2 - Reserved_2: Reserved 3 - Disabled: Host disable clock to DPM request. DPM clock may be gated if not other outstanding host requests.
15-14	Reserved	R/W	0h	
13-12	TA_CLKO	R/W	0h	Clock gating control override for the TA 0 - Reserved_0: Reserved 1 - Enabled: Clock to the TA is enabled 2 - Reserved_2: Reserved 3 - Disabled: Host disable clock to TA request. TA clock may be gated if not other outstanding host requests.
11-10	Reserved	R/W	0h	
9-8	TSP_CLKO	R/W	0h	Clock gating control override for the TSP 0 - Reserved_0: Reserved 1 - Enabled: Clock to the TSP is enabled 2 - Reserved_2: Reserved 3 - Disabled: Host disable clock to TSP request. TSP clock may be gated if no other outstanding host requests.
7-6	Reserved	R/W	0h	
5-4	ISP_CLKO	R/W	0h	Clock gating control override for the ISP 0 - Reserved_0: Reserved 1 - Enabled: Clock to the ISP is enabled 2 - Reserved_2: Reserved 3 - Disabled: Host disable clock to ISP request. ISP clock may be gated if no other outstanding host requests.
3-2	Reserved	R/W	0h	
1-0	Reserved	R/W	0h

6.1 GPMC

6.1.1 Introduction

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

6.1.1.1 GPMC Features

The general features of the GPMC module include:

- Data path to external memory device can be 16- or 8-bit wide
- 32-bit OCPIP 2.0 compliant core, single slave interface. Support non-wrapping and wrapping burst up to 16x32bits.
- Support secure transactions controlled by security firewall
- Up to 62.5 MHz external memory clock performance (single device) with L3 clock of 125 MHz
- Support for the following memory types:
  - External asynchronous or synchronous 8-bit width memory or device (non burst device)
  - External asynchronous or synchronous 16-bit width memory or device
  - External 16-bit non-multiplexed NOR Flash device
  - External 16-bit address and data multiplexed NOR Flash device
  - External 8-bit and 16-bit NAND flash device
  - External 16-bit pSRAM device
- Support of Error Code detection using BCH code (t=4, 8 or 16) or Hamming code for 8-bit or 16-bit NAND-flash, organized with page size of 512 Byte, 1Kbytes or more.
- Support 1 GBytes maximum addressing capability which can be divided into 8 independent chip-select with programmable bank size and base address on 16 MBytes, 32 MBytes, 64 MBytes, 128 MBytes boundary
- Fully pipelined operation for optimal memory bandwidth usage
- Support external device clock frequency of 1, 2, 3 and 4 divider from L3 clock.
- Support programmable auto-clock gating when there is no access.
- Support Midlereq/SidleAck protocol
- Support the following interface protocols when communicating with external memory or external devices.
  - Asynchronous read/write access
  - Asynchronous read page access (4-8-16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4-8-16 Word16)
  - Synchronous read burst access with wrap capability (4-8-16 Word16)
- Address and Data multiplexed access
- Each chip-select as independent and programmable control signal timing parameters for Setup and Hold time. Parameters are set according to the memory device timing parameters, with one L3 clock cycle timing granularity.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pins monitoring (up to 4 WAIT pins)
- Support bus keeping

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

- Support bus turn around
- Pre-fetch and write posting engine associated with system DMA to get full performance from NAND device with minimum impact on NOR/SRAM concurrent access.
- On the fly ECC Hamming Code calculation to improve NAND usage reliability with minimum impact on SW

6.1.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

Figure 6-1 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 6-1. GPMC Block Diagram

6.1.1.3 Unsupported GPMC Features

The following module features are not supported in this device.

Table 6-1. Unsupported GPMC Features

Feature	Reason
Chip Select 7	Not pinned out
32-bit devices	Only 16 data lines pinned out
WAIT[3:2]	Not pinned out. All CS regions must use WAIT0 or WAIT1

6.1.2 Integration

An instantiation of GPMC provides this device with access to NAND Flash, NOR Flash, and other asynchronous and synchronous interface peripherals. Figure 6-2 shows the integration of the GPMC module in this device.

Figure 6-2. GPMC Integration

6.1.2.1 GPMC Connectivity Attributes

The general connectivity attributes for the GPMC module are shown in Table 6-2.

Table 6-2. GPMC Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to Sabertooth
DMA Requests	1 DMA request to EDMA
Physical Address	L3 Slow Slave Port Memory and control register regions qualified with MAddressSpace bit

6.1.2.2 GPMC Clock and Reset Management

The GPMC is a synchronous design and operates from the same clock as the Slow L3. All timings use this clock as a reference.

Table 6-3. GPMC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_gpmc_clk Interface / Functional clock	100 MHz	CORE_COLKOUTM4 / 2	pd_per_l3s_gclk From PRCM

6.1.2.3 GPMC Pin List

The GPMC external interface signals are shown in Table 6-4.

Table 6-4. GPMC Pin List

Pin	Type	Description
GPMC_A[27:0]	O	Address outputs
GPMC_AD[15:0]	I/O	Data - multiplexed with Address[16:1] and Address[27:12]
GPMC_CS[7:0]n	O	Chip selects (active low)
GPMC_CLK	O	Synchronous mode clock
GPMC_CLKRET	I	Synchronous mode return clock
GPMC_ADVn_ALE	O	Address Valid or Address Latch Enable depending if NOR or NAND protocol memories are selected.
GPMC_OEn_REn	O	Output Enable (active low). Also used as Read Enable (active low) for NAND protocol memories
GPMC_WEn	O	Write Enable (active low)

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Table 6-4. GPMC Pin List (continued)

Pin	Type	Description
GPMC_BE0n_CLE	O	Lower Byte Enable (active low). Also used as Command Latch Enable for NAND protocol memories
GPMC_BE1n	O	Upper Byte Enable (active low)
GPMC_WPn	O	Write Protect (active low)
GPMC_WAIT[3:0]	I	External wait signal for NOR and NAND protocol memories.
GPMC_IO_DIR2	O	GPMC.D[15:0] signal direction control (high when transmit – for external xcvr)

6.1.3 Functional Description

6.1.3.1 GPMC Signals

Table 6-5 lists the GPMC subsystem I/O pins.

NOTE: The $\overline{\text{GPMC_CS[7:6]}}$ and GPMC_WAIT1 pins are not available on all devices, refer to your device-specific data manual for availability.

Table 6-5. GPMC I/O Description

Pin Name	I/O	Description
GPMC_A[27:0]	O	Address
GPMC_D[15:0]	I/O	Data
$\overline{\text{GPMC_CS[7:0]}}$	O	Chip-selects (active low)
GPMC_CLK	O	Clock generated for the external memory or device
GPMC_$\overline{\text{ADV}}$_ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
$\overline{\text{GPMC_OE_RE}}$	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
$\overline{\text{GPMC_WE}}$	O	Write enable (active low)
GPMC_$\overline{\text{BE0}}$_CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
$\overline{\text{GPMC_BE1}}$	O	Upper-byte enable (active low).
$\overline{\text{GPMC_WP}}$	O	Write protect (active low)
GPMC_WAIT[1:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.
GPMC_DIR	O	GPMC_D[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory) High during receive (for read access: data IN from memory to GPMC)

Table 6-6 shows the use of address and data GPMC controller pins based on the type of external device.

Table 6-6. GPMC Pin Multiplexing Options

GPMC_D[14]	D14	Not Used	A15/D14	D14	Not Used
GPMC_D[13]	D13	Not Used	A14/D13	D13	Not Used
GPMC_D[12]	D12	Not Used	A13/D12	D12	Not Used
GPMC_D[11]	D11	Not Used	A12/D11	D11	Not Used
GPMC_D[10]	D10	Not Used	A11/D10	D10	Not Used
GPMC_D[9]	D9	Not Used	A10/D9	D9	Not Used
GPMC_D[8]	D8	Not Used	A9/D8	D8	Not Used
GPMC_D[7]	D7	D7	A8/D7	D7	D7
GPMC_D[6]	D6	D6	A7/D6	D6	D6
GPMC_D[5]	D5	D5	A6/D5	D5	D5
GPMC_D[4]	D4	D4	A5/D4	D4	D4
GPMC_D[3]	D3	D3	A4/D3	D3	D3
GPMC_D[2]	D2	D2	A3/D2	D2	D2
GPMC_D[1]	D1	D1	A2/D1	D1	D1
GPMC_D[0]	D0	D0	A1/D0	D0	D0

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field (i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

6.1.3.2 GPMC Modes

This section shows three GPMC external connections options:

- Figure 6-3 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- Figure 6-4 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 6-5 shows a connection between the GPMC and a 8-bit NAND device

6.1.3.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (eDMA) request
- One interrupt request to the Cortex-A8 MPU Interrupt Controller (MA_IRQ)
- One clock for functional and interface domains

Figure 6-6 shows GPMC integration. Table 6-7 through Table 6-9 summarize the integration of the module in the device.

6.1.3.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time

6.1.3.4.1 GPMC Clock Configuration

Table 6-10 describes the GPMC clocks.

Table 6-10. GPMC Clocks

Signal	I/O	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices.

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 6-8. The GPMC_CLK is configured via the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 6-11.

Table 6-11. GPMC_CONFIG1_i Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/4
	11	GPMC_FCLK/8

6.1.3.4.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

6.1.3.4.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 6-12 describes power-management features available for the GPMC module.

Table 6-12. GPMC Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE] bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4-3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

6.1.3.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in Figure 6-6.

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A8 MPU subsystem: A_IRQ_100

Table 6-13 lists the event flags, and their mask, that can cause module interrupts.

Table 6-13. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTATUS[9] WAIT1EDGEDETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGEDETECTIONENABLE	Edge	A_IRQ_100	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGEDETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGEDETECTIONENABLE	Edge	A_IRQ_100	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS	GPMC_IRQENABLE[1] TERMINALCOUNTENABLE	Level	A_IRQ_100	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	A_IRQ_100	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG[2] DMAMODE bit shall be cleared to 0.

6.1.3.4.5 GPMC DMA Requests

The GPMC generates one DMA event as shown in Figure 6-6.

- From GPMC (GPMC_DMA_REQ) to the eDMA: e_DMA_53

6.1.3.4.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field ([24-23]) according to the effective attached device page length and to enable the GPMC_CONFIG1_i WRAPBURST bit ([31]) if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

6.1.3.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC_D[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0] and GPMC I/O: GPMC_D[15-8].

6.1.3.4.7.1 GPMC I/O Configuration Setting

NOTE: In this section and next sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 10b
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 10b

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 01b

To select an address/data-nonmultiplexed device , program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

6.1.3.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 6.1.5 provides the GPMC register locations. For the map of GPMC memory locations, see Table 6-59.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

6.1.3.4.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see Table 6-59.

The GPMC 512 Mbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 Mbytes to 256 Mbytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 6-7 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

Figure 6-7. Chip-Select Address Mapping and Decoding Mask

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, i = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

6.1.3.4.8.2 Access Protocol

6.1.3.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 6.1.3.4.12 and Section 6.1.3.4.12.1.

6.1.3.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE field (i = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

6.1.3.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[[9-8] MUXADDDATA bit field (i = 0 to 7). The $\overline{ADV}$ signal must be used as the external device address latch control signal. For the associated chip-select configuration, $\overline{ADV}$ assertion and deassertion time and $\overline{OE}$ assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see Section 6.1.3.3).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see Section 6.1.3.4.12).

6.1.3.4.8.3 External Signals

6.1.3.4.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin:gpmc_wait1, and gpmc_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit field (where i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

Copyright © 2011, Texas Instruments Incorporated

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

6.1.3.4.8.3.2 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME field (i = 0 to 7).

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 6-8 shows wait behavior during an asynchronous single read access.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Figure 6-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 00b or 01b.

6.1.3.4.8.3.3 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME fields (i = 0 to 7).

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

6.1.3.4.8.3.4 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 6-9 shows wait behavior during a synchronous read burst access.

Figure 6-9. Wait Behavior During a Synchronous Read Burst Access

The WAIT signal is active low. WAITMONITORINGTIME = 00b or 01b.

6.1.3.4.8.3.5 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field equal to 0 or 1, respectively).

6.1.3.4.8.3.6 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 6.1.3.4.12.2.

6.1.3.4.8.3.7 Idle Cycle Control Between Successive Accesses

6.1.3.4.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the $\overline{CS}$/$\overline{OE}$ de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after $\overline{CS}$ or $\overline{OE}$ de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See Figure 6-10 to Figure 6-12.

Another way to prevent bus contention is to define an earlier $\overline{CS}$ or $\overline{OE}$ deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

Figure 6-12. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround

6.1.3.4.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

6.1.3.4.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{OE}$_$\overline{RE}$, $\overline{WE}$) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals ($\overline{WE}$, $\overline{OE}$_$\overline{RE}$) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 6.1.3.4.8.3.7.1 for more details on bus turnaround.

Table 6-14 describes the configuration required for idle cycle insertion.

Table 6-14. Idle Cycle Insertion Configuration

First Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Addr/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	>0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	>0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	>0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

6.1.3.4.8.3.8 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

Copyright © 2011, Texas Instruments Incorporated

6.1.3.4.8.3.9 GPMC_DIR Pin

The GPMC_DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15-0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required. The GPMC_DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the GPMC_DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the GPMC_DIR pin goes from OUT to IN at $\overline{OE}$ assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The GPMC_DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the GPMC_DIR pin is OUT (see Section 6.1.3.4.9.10). In nonmultiplexed devices, the GPMC_DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

6.1.3.4.8.3.10 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Power, Reset, and Clock Management.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

6.1.3.4.8.3.11 Write Protect Signal ($\overline{WP}$)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The $\overline{GPMC_WP}$ output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

6.1.3.4.8.3.12 Byte Enable ($\overline{BE1}/\overline{BE0}$)

Byte enable signals ($\overline{BE1}/\overline{BE0}$) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

6.1.3.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0]ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.

Copyright © 2011, Texas Instruments Incorporated

- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the

9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

6.1.3.4.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see Section 6.1.3.4.9.6.

In the following sections, the start access time refer to the time at which the access begins.

6.1.3.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME fields (i = 0 to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{OE}$_$\overline{RE}$, $\overline{WE}$, and $\overline{BE0}$_CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals ($\overline{CS}$, $\overline{ADV}$_ALE, $\overline{BE0}$_CLE, $\overline{WE}$, and $\overline{OE}$_$\overline{RE}$) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

6.1.3.4.9.2 $\overline{CS}$: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME field (where i = 0 to 7) defines the $\overline{CS}$ signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the $\overline{CS}$ signal deassertion time relative to start access time.

Copyright © 2011, Texas Instruments Incorporated

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

$\overline{CS}$ signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the $\overline{CS}$ assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling $\overline{CS}$ transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the $\overline{CS}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

6.1.3.4.9.3 $\overline{ADV}$/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field (where i = 0 to 7) defines the $\overline{ADV}$_ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the $\overline{ADV}$_ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before $\overline{ADV}$_ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after $\overline{ADV}$_ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

$\overline{ADV}$_ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{ADV}$_ALE assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling $\overline{ADV}$_ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than $\overline{ADV}$_ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

The GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high $\overline{ADV}$ pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, $\overline{ADV}$ is kept low until it reaches the correct ADVxxOFFTIME.

See Section 6.1.3.4.12 for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

Copyright © 2011, Texas Instruments Incorporated

6.1.3.4.9.4 $\overline{OE}$/$\overline{RE}$: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME field (where i = 0 to 7) defines the $\overline{OE}$_$\overline{RE}$ signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME field defines the $\overline{OE}$_$\overline{RE}$ signal deassertion time relative to start access time. It is applicable only to read accesses. $\overline{OE}$_$\overline{RE}$ is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before $\overline{OE}$_$\overline{RE}$ assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{OE}$_$\overline{RE}$ assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the $\overline{OE}$ signal de-asserted before $\overline{OE}$ can be asserted again to define a read command.

The $\overline{OE}$_$\overline{RE}$ signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{OE}$_$\overline{RE}$ assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling $\overline{OE}$_$\overline{RE}$ transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than $\overline{OE}$_$\overline{RE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time.

6.1.3.4.9.5 $\overline{WE}$: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME field (where i = 0 to 3) defines the $\overline{WE}$ signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME field defines the $\overline{WE}$ signal-deassertion time relative to start access time. These bit fields only apply to write accesses. $\overline{WE}$ is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before $\overline{WE}$ assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after $\overline{WE}$ assertion.

$\overline{WE}$ signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on $\overline{WE}$ assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling $\overline{WE}$ transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the $\overline{WE}$ signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

6.1.3.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field (i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

6.1.3.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field (i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

6.1.3.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME (i = 0 to 7). This allows $\overline{OE}$ and GPMC data capture timing parameters to be independent of $\overline{WE}$ and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

6.1.3.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i[[20-16] RDACCESSTIME field (i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4-0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 6.1.3.4.8.1.

6.1.3.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 6.1.3.4.8.1.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 6.1.3.4.8.1.

6.1.3.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field (i = 0 to 7) can be set with a granularity of 1 or 2 throught the GPMC_CONFIG1_i[[4] TIMEPARAGRANULARITY.

6.1.3.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 6.1.3.4.8.1.

6.1.3.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 6.1.3.4.8.1.

6.1.3.4.9.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

6.1.3.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (i = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and $\overline{\text{BE[1:0]}}$ are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

6.1.3.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

6.1.3.4.10.1.1 Access on Address/Data Multiplexed Devices

6.1.3.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 6-13 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 6-13. Asynchronous Single Read Operation on an Address/Data Multiplexed Device

6.1.3.4.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 6.1.3.10.1 for formulas to calculate timing parameters.

Table 6-45 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 6.1.3.4.8.2.3.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[25:16] are placed on the address bus. The address phase ends at $\overline{OE}$ assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field. It controls the address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field. It controls the address hold time from $\overline{CS}$ deassertion
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[[3-0] OEONTIME field.
  - OE deassertion time is controlled by the GPMC_CONFIG4_i[[12-8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that $\overline{OE}$ is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 6.1.3.4.10.5. Between two successive accesses, if an $\overline{CS}$ pulse is needed:

- The GPMC_CONFIG6_i[[11-8] CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i[[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 6-14 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

Figure 6-14. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 × 16-Bit Read)

6.1.3.4.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 6-15 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 6-15. Asynchronous Single Write on an Address/Data-Multiplexed Device

6.1.3.4.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See Section 6.1.3.10.1 for formulas to calculate timing parameters.

Table 6-45 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until $\overline{WE}$ assertion time. For more information, see Section 6.1.3.4.8.2.3.

The $\overline{CS}$ and $\overline{ADV}$ signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a write cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 6.1.3.4.9.10.

6.1.3.4.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 6.1.3.4.10.3.

6.1.3.4.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

6.1.3.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 6-16 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 6-16. Asynchronous Single-Read on an AAD-Multiplexed Device

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.1.3.4.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See Section 6.1.3.10.1 for formulas to calculate timing parameters.

Table 6-45 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The first address phase ends at the first $\overline{OE}$ deassertion time. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The second address phase ends at the second $\overline{OE}$ assertion time, when the DIR signal goes from OUT to IN.

The $\overline{CS}$ and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$. $\overline{ADV}$ is asserted and deasserted twice during a read transaction:
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$. $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle):
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

6.1.3.4.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 6-17 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 6-17. Asynchronous Single Write on an AAD-Multiplexed Device

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

See Section 6.1.3.10.1 for formulas to calculate timing parameters.

Table 6-45 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$, $\overline{WE}$, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a write transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted during the address phase of a write transaction
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until $\overline{OE}$ deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

6.1.3.4.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 6.1.3.4.10.3.

6.1.3.4.10.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see Section 6.1.3.4.10.3.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field. In the following section, i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

6.1.3.4.10.2.1 Synchronous Single Read

Figure 6-18 and Figure 6-19 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 6-18. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Figure 6-19. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

See Section 6.1.3.10.1 for formulas to calculate timing parameters.

Table 6-45 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 6.1.3.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output enable signal $\overline{OE}$
  - $\overline{OE}$ assertion indicates a read cycle.
  - $\overline{OE}$ assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i[4-0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

- Direction signal DIR: DIR goes from OUT to IN at the same time as $\overline{OE}$ assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 6.1.3.4.9.10.

6.1.3.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 6-20 and Figure 6-21 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 6-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Figure 6-21. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When GPMC_CONFIG5_i[20-16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The $\overline{CS}$, $\overline{ADV}$, $\overline{OE}$ and DIR signals are controlled in the same way as for synchronous single read operation. See Section 6.1.3.4.10.2.1.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 6-20, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 6.1.3.4.9.10.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH.

6.1.3.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see Figure 6-22).

Figure 6-22. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until [19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

Copyright © 2011, Texas Instruments Incorporated

Figure 6-24. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until $\overline{OE}$ assertion time. For details, see Section 6.1.3.4.8.2.3.

- Chip-select signal $\overline{CS}$
  - $\overline{CS}$ assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field (i = 0 to 7) and ensures address setup time to $\overline{CS}$ assertion.
  - $\overline{CS}$ deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME field and ensures address hold time to $\overline{CS}$ deassertion.
- Address valid signal $\overline{ADV}$
  - $\overline{ADV}$ assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - $\overline{ADV}$ deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.

Copyright © 2011, Texas Instruments Incorporated

- Write enable signal $\overline{WE}$
  - $\overline{WE}$ assertion indicates a read cycle.
  - $\overline{WE}$ assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - $\overline{WE}$ deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.

  The $\overline{WE}$ falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the $\overline{WE}$ signal at low during the address phase.
- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with $\overline{OE}$ driven low. The second phase for LSB address is qualified with $\overline{OE}$ driven high. The address phase ends at $\overline{WE}$ assertion time.

The $\overline{CS}$ and DIR signals are controlled as detailled above.

- Address valid signal $\overline{ADV}$ is asserted and deasserted twice during a read transaction
  - $\overline{ADV}$ first assertion time is controlled by the GPMC_CONFIG3_i[[6-4] ADVAADMUXONTIME field.
  - $\overline{ADV}$ first deassertion time is controlled by the GPMC_CONFIG3_i[[26-24] ADVAADMUXRDOFFTIME field.
  - $\overline{ADV}$ second assertion time is controlled by the GPMC_CONFIG3_i[[3-0] ADVONTIME field.
  - $\overline{ADV}$ second deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.
- Output Enable signal $\overline{OE}$ is asserted and deasserted twice during a read transaction ($\overline{OE}$ second assertion indicates a read cycle)
  - $\overline{OE}$ first assertion time is controlled by the GPMC_CONFIG4_i[[6-4] OEAADMUXONTIME field.
  - $\overline{OE}$ first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME field.
  - $\overline{OE}$ second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - $\overline{OE}$ second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from $\overline{CS}$ deassertion. In Figure 6-24 the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 6.1.3.4.9.10.

6.1.3.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-multiplexed mode.

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

6.1.3.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 6-27 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 6-27. Asynchronous Multiple (Page Mode) Read

The WAIT signal is active low.

$\overline{CS}$, $\overline{ADV}$, $\overline{OE}$ and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 6.1.3.4.10.1.1.2.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time (i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the $\overline{CS}$ deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME field.
- In Figure 6-27, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

6.1.3.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 6.1.3.7.

6.1.3.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

6.1.3.4.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field (i = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

6.1.3.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[[11-10] DEVICETYPE field (i = 0 to 3) shall be cleared to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum $\overline{CS}$ high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

6.1.3.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

6.1.3.4.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Copyright © 2011, Texas Instruments Incorporated

Any chip-select region can be qualified as a NAND region to constrain the $\overline{\text{ADV}}$_ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the $\overline{\text{BE0}}$_CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

6.1.3.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 6-15. Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

Table 6-15. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i	0	Single access
READTYPE	GPMC_CONFIG1_i	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i	0	Single access
WRITETYPE	GPMC_CONFIG1_i	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i	Don't care	Asynchronous mode

6.1.3.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with $\overline{OE}$ and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i register location and to the GPMC_NAND_ADDRESS_i register location must be posted for faster operations (i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i (i = 0 to 7) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

6.1.3.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- $\overline{CE}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 6-28 shows the NAND command latch cycle.

CLE is shared with the $\overline{BE0}$ output signal and has an inverted polarity from $\overline{BE0}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, $\overline{BE0}$ (also $\overline{BE1}$) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

Figure 6-28. NAND Command Latch Cycle

6.1.3.4.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 6-29 shows the NAND address latch cycle.

ALE is shared with the $\overline{ADV}$ output signal and has an inverted polarity from $\overline{ADV}$. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

6.1.3.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable $\overline{RE}$ or $\overline{WE}$ signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- $\overline{CS}$ is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- $\overline{RE}$ is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of $\overline{RE}$ high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after $\overline{RE}$ deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and $\overline{WE}$ are maintained inactive.

Figure 6-30 shows the NAND data read cycle.

Figure 6-30. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- $\overline{CS}$ is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- $\overline{WE}$ is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and $\overline{RE}$ ($\overline{OE}$) are maintained inactive.

Figure 6-31 shows the NAND data write cycle.

Figure 6-31. NAND Data Write Cycle

6.1.3.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by $\overline{CS}$-to-data-valid timing and has faster $\overline{RE}$-to-data-valid timing. Successive accesses with $\overline{CS}$ deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that $\overline{CS}$ always stays low between two accesses to the same chip-select. Moreover, an $\overline{CS}$ deassertion time between the same chip-select NAND accesses is likely to be required as follows: the $\overline{CS}$ deassertion requires programming CYCLETIME and RDACCESSTIME according to the $\overline{CS}$-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum $\overline{CS}$ high pulse width between accesses. For more information about optimal prefetch engine access, see Section 6.1.3.4.12.4.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum $\overline{CS}$ high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important $\overline{RE}$ high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

6.1.3.4.12.1.7 Read and Write Access Size Adaptation

6.1.3.4.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

6.1.3.4.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Copyright © 2011, Texas Instruments Incorporated

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

6.1.3.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 µs) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 1) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE [11-8]bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

6.1.3.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (x = 0 or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

6.1.3.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1

Copyright © 2011, Texas Instruments Incorporated

to the WAITxEDGEDETECTIONSTATUS bit (x = 0 or 1) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

6.1.3.4.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhurl-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

6.1.3.4.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

6.1.3.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZE bits are cleared to 0, and the ECC9RESULTSIZE bit is set to 1.

6.1.3.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 6-16 describes the ECC enable settings.

Table 6-16. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3h	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7h	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7h	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

6.1.3.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 6-32 and Figure 6-33. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 6-32. Hamming Code Accumulation Algorithm (1 of 2)

Copyright © 2011, Texas Instruments Incorporated

For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Unused parity bits in the result registers are cleared to 0.

Figure 6-33. Hamming Code Accumulation Algorithm (2 of 2)

Figure 6-34 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 6-34. ECC Computation for a 256-Byte Data Stream (Read or Write)

Copyright © 2011, Texas Instruments Incorporated

Figure 6-35 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

Figure 6-35. ECC Computation for a 512-Byte Data Stream (Read or Write)

6.1.3.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

6.1.3.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

6.1.3.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 6-36 and Figure 6-37.

6.1.3.4.12.3.2 BCH Code (Bose-Chaudhurl-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

6.1.3.4.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

6.1.3.4.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree 2 - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 6-17.

Table 6-17. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)	ECC R(x)				
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) - 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in , , , and (where i = 0 to 7).

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

6.1.3.4.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 * x + b6 * x + ... + b0 * x
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

Table 6-18 and Table 6-19 show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^12-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 6-18. Aligned Message Byte Mapping in 8-bit NAND

Byte Offset	8-Bit Word
0	(msb) Byte 511 (1FFh)

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

6.1.3.4.12.3.2.4 Memory Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

6.1.3.4.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 6.1.3.4.12.3.3.

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

6.1.3.4.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

Figure 6-38 shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

Figure 6-38. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

6.1.3.4.12.3.2.7 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

6.1.3.4.12.3.2.8 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

6.1.3.4.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 6.1.3.4.12.3.2.3.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 6-39 to Figure 6-41, tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of n = 2 - 1 = 8191 bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (Figure 6-39: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (Figure 6-39: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (Figure 6-39: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

6.1.3.4.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 6-39), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 6-39. NAND Page Mapping and ECC: Per-Sector Schemes

6.1.3.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

6.1.3.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectivelly uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

6.1.3.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (i.e., reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 6.1.3.4.12.2.2. The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT field.

Table 6-26 describes the prefetch mode configuration.

Table 6-26. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Prefetch engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG1		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 6.1.3.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONFIG1	1	Starts the prefetch engine

6.1.3.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is trigerred. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

Copyright © 2011, Texas Instruments Incorporated

6.1.3.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 6-27. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Write-posting engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 6.1.3.4.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL	1	Starts the prefetch engine

6.1.3.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

6.1.3.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated $\overline{CS}$ signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i(where , i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 6-42, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field.

6.1.3.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finnaly back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

6.1.3.5 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. Figure 6-43 shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. Table 6-28 and Table 6-29 list each step in the model.

6.1.3.7 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC. Table 6-31 through Table 6-35 list the steps to configure the GPMC in NOR mode.

NOTE: In the tables of this section, 'x' in Value column stands for 'depends on configuration'.

Table 6-31. NOR Memory Type

Sub-process Name	Register / Bitfield	Value
Set the NOR protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	0
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

Table 6-32. NOR Chip-Select Configuration

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 6-33. NOR Timings Configuration

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in various memory modes	See Section 6.1.3.10	

Table 6-34. WAIT Pin Configuration

Sub-process Name	Register / Bitfield	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

6.1.3.8 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to NAND memory connected to the GPMC.

Table 6-36. NAND Memory Type

Sub-process Name	Register / Bitfield	Value
Set the NAND protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	2h
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_i[9] MUXADDDATA	0
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See Section 6.1.3.9	x

Table 6-37. NAND Chip-Select Configuration

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

Table 6-38. Asynchronous Read and Write Operations

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in asynchronous modes	See Section 6.1.3.10	

Table 6-39. ECC Engine

Sub-process Name	Register / Bitfield	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 and GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1	x
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_SIZE_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_SIZE_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_SIZE_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_SIZE_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_SIZE_CONFIG[6-4] ECCTOPSECTOR	x

6.1.3.10.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

6.1.3.10.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 2h. Table 6-46 details NAND timing parameters.

Table 6-46. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - $\overline{\text{GPMC_WE}}$ valid time
B	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ valid
C	ns	Delay time - GPMC_$\overline{\text{BE0}}$_CLE/GPMC_$\overline{\text{ADV}}$_ALE high to $\overline{\text{GPMC_WE}}$ valid
D	ns	Delay time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_WE}}$ valid
E	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_AD[15:0] invalid
F	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to GPMC_$\overline{\text{BE0}}$_CLE/GPMC_$\overline{\text{ADV}}$_ALE invalid
G	ns	Delay time - $\overline{\text{GPMC_WE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ valid
J	ns	Setup time - GPMC_AD[15:0] valid to $\overline{\text{GPMC_OE}}$ invalid
K	ns	Pulse duration - $\overline{\text{GPMC_OE}}$ valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - $\overline{\text{GPMC_OE}}$ invalid to $\overline{\text{GPMC_CS}}$ invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEExtraDelay)) * GPMC_FCLK period

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 6-45 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 6-45. NAND Command Latch Cycle Timing Simplified Example

6.1.3.10.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 6-47. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - $\overline{\text{GPMC_CS}}$ low
B	ns	Delay time - address bus valid to GPMC_CLK first edge
		Delay time - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ valid to GPMC_CLK first edge
C	ns	Pulse duration - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ low
D	ns	Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ invalid
		Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{ADV}}$_ALE invalid
E	ns	Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_CS}}$ invalid
		Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_OE}}$ invalid
F	ns	Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_CS}}$ transition
G	ns	Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{ADV}}$_ALE transition
H	ns	Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_OE}}$ transition
I	ns	Delay time - GPMC_CLK rising edge to $\overline{\text{GPMC_WE}}$ transition
J	ns	Delay time - GPMC_CLK rising edge to GPMC_AD data bus transition
		Delay time - GPMC_CLK rising edge to GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ transition
K	ns	Pulse duration - GPMC_$\overline{\text{ADV}}$_ALE low
L	ns	Delay time - GPMC_WAIT invalid to first data latching GPMC_CLK edge

DRAFT ONLY

The configuration parameters are calculated through the following formulas.

For single read accesses:

A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (RDCYCLETIME - ACCESSTIME) * GPMC_FCLK period

E = (CSRDOFFTIME - ACCESSTIME) * GPMC_FCLK period

For burst read accesses (where n is the page burst access number):

A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (RDCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

E = (CSRDOFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

For burst write accesses (where n is the page burst access number):

A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (WRCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

E = (CSWROFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

For all accesses:

For $\overline{CS}$ falling edge ($\overline{CS}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME -

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{CS}$ rising edge ($\overline{CS}$ de-activated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ falling edge ($\overline{ADV}$ activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ rising edge ($\overline{ADV}$ de-activated) in reading mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For $\overline{ADV}$ rising edge ($\overline{ADV}$ de-activated) in writing mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and

For $\overline{WE}$ rising edge ($\overline{WE}$ de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For GPMC_$\overline{ADV}$ low pulse duration:

- Read operation

  K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation

  K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 6-46 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

6.1.3.10.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when [11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 6-48. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - $\overline{\text{GPMC_CS}}$ low
B	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_$\overline{\text{ADV}}$_ALE invalid
C	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ valid
F	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_WE}}$ invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before $\overline{\text{GPMC_OE}}$ high
I	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ invalid (burst read)
J	ns	Delay time - address bus valid to $\overline{\text{GPMC_CS}}$ valid
		Delay time - data bus valid to $\overline{\text{GPMC_CS}}$ valid
		Delay time - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ valid to $\overline{\text{GPMC_CS}}$ valid
K	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_$\overline{\text{ADV}}$_ALE valid
L	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to $\overline{\text{GPMC_OE}}$ valid
M	ns	Delay time - GPMC_CS valid to first data latching edge
N	ns	Pulse duration - GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ valid time
O	ns	Delay time - $\overline{\text{GPMC_CS}}$ valid to GPMC_$\overline{\text{ADV}}$_ALE valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

$\overline{\text{GPMC_CS}}$ low pulse:

For single read: A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst read: A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

For single write: A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst write: A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

$\overline{\text{GPMC_CS}}$ valid to GPMC_$\overline{\text{ADV}}$_ALE invalid delay:

For reading: B = ((ADVRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

For writing: B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

C = ((OEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

F = ((WEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

G = CYCLE2CYCLEDELAY * GPMC_FCLK period

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

H = ((OEOFFTIME - ACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period

I = ((OEOFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number

J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period

K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period M = ((ACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC_FCLK period

GPMC_$\overline{\text{BE0}}$_CLE/$\overline{\text{GPMC_BE1}}$ pulse:

For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst read: N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

For burst write: N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

Figure 6-47 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 6-47. Asynchronous NOR Single Write Simplified Example

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

6.1.4 Use Cases

6.1.4.1 How to Set GPMC Timing Parameters for Typical Accesses

6.1.4.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

6.1.4.1.2 Typical GPMC Setup

Table 6-49 lists some of the I/Os of the GPMC module.

Table 6-49. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[27:17]	O	Address
GPMC_D[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
$\overline{\text{GPMC_CSx}}$	O	Chip-select (where x = 0, or 1)
GPMC_$\overline{\text{ADV}}$_ALE	O	Address valid enable
$\overline{\text{GPMC_OE_RE}}$	O	Output enable (read access only)
$\overline{\text{GPMC_WE}}$	O	Write enable (write access only)
GPMC_WAIT[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 6-48 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 6-48. GPMC Connection to an External NOR Flash Memory

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

DRAFT

Copyright © 2011, Texas Instruments Incorporated

6.1.4.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 6-50 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 6-51 shows how to calculate timings for the GPMC using the memory parameters.

Figure 6-49 shows the synchronous burst read access.

Table 6-50. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	$\overline{CS}$ setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Impedance	7
tOEZ	Output enable to High-Impedance	7
tAVC	$\overline{ADV}$ setup time	6
tAVD	$\overline{AVD}$ pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: $\overline{CS}$/$\overline{OE}$ hold time ($\overline{CS}$ and $\overline{OE}$ must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

6.1.4.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 6-52 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 6-53 shows how to calculate timings for the GPMC using the memory parameters.

Figure 6-50 shows the asynchronous read access.

Table 6-52. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from $\overline{CS}$ low	80
tAAVDS	Address setup time to rising edge of $\overline{ADV}$	3
tAVDP	$\overline{ADV}$ low time	6
tCAS	$\overline{CS}$ setup time to $\overline{ADV}$	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Impedance	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 6-53: the number of clock cycles between the address capture ($\overline{ADV}$ rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configure to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no $\overline{OE}$/$\overline{CS}$ deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).
- To complete the access, $\overline{OE}$/$\overline{CS}$ signals are driven to high-impedance. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

6.1.4.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 6-54 shows how to calculate timings for the GPMC using the memory parameters.

Table 6-55 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 6-51 shows the synchronous burst write access.

Table 6-54. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	$\overline{ADV}$ low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	$\overline{CS}$ setup time to $\overline{WE}$	3
tCAS	$\overline{CS}$ setup time to $\overline{ADV}$	0
tAVSC	$\overline{ADV}$ setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires 1 cycle of data hold time ($\overline{CS}$ de-assertion).

6.1.4.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

6.1.4.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, , ...)
- 8- and 16-bit NAND flash device

6.1.4.2.2 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories (see Table 6-56).

Table 6-56. Supported Memory Interfaces

6.1.4.2.3 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 6-57 summarizes the NAND interface signals level applied to external device or memories.

Table 6-57. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	$\overline{CE}$	$\overline{WE}$	$\overline{RE}$	$\overline{WP}$
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H	H	H	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L

6.1.4.2.4 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; i.e., it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 6-58 summarizes the NOR interface signals level applied to external device or memories.

Table 6-58. NOR Interface Bus Operations Summary

Bus Operation	CLK	$\overline{ADV}$	$\overline{CS}$	$\overline{OE}$	$\overline{WE}$	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

6.1.4.2.5 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventionnal NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

6.1.4.2.6 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

6.1.4.2.7 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 512 MBytes divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

6.1.5 GPMC Registers

Table 6-59 provides a summary of the GPMC registers. All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except the GPMC_NAND_DATA_i register, are little endian. If the GPMC_NAND_DATA_i register is accessed, the endianness is access-dependent.

In this section, i corresponds to the chip-select number, i = 0 to 7.

Table 6-59. GPMC Registers

6.1.5.1 GPMC_REVISION

This register contains the IP revision code.

Figure 6-52. GPMC_REVISION

31–16	15–8	7–0
Reserved	Reserved	REV
R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 6-60. GPMC_REVISION Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	REV	0-FFh	IP revision. Major revision is [7-4]. Minor revision is [3-0]. Examples: 10h for revision 1.0, 21h for revision 2.1.

6.1.5.2 GPMC_SYSCONFIG

This register controls the various parameters of the OCP interface.

Figure 6-53. GPMC_SYSCONFIG

31–16	15–5	4–3	2	1	0
Reserved	Reserved	SIDLEMODE	Rsvd	SOFTRESET	AUTOIDLE
R-0	R-0	R/W	R-0	R/W	R/W

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 6-61. GPMC_SYSCONFIG Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-3	SIDLEMODE		Idle mode
		0	Force-idle. An idle request is acknowledged unconditionally
		1h	No-idle. An idle request is never acknowledged
		2h	Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module
		3h	Reserved
2	Reserved	0	Reserved
1	SOFTRESET		Software reset (Set 1 to this bit triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0)
		0	Normal mode
		1	The module is reset
0	AUTOIDLE		Internal OCP clock gating strategy
		0	Interface clock is free-running
		1	Automatic Interface clock gating strategy is applied, based on the Interconnect activity

R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 6-63. GPMC_IRQSTATUS Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1EDGEDETECTIONSTATUS		Status of the Wait1 Edge Detection interrupt
		R0	A transition on WAIT1 input pin has not been detected
		W0	WAIT1EDGEDETECTIONSTATUS bit unchanged
		R1	A transition on WAIT1 input pin has been detected
		W1	WAIT1EDGEDETECTIONSTATUS bit is reset
8	WAIT0EDGEDETECTIONSTATUS		Status of the Wait0 Edge Detection interrupt
		R0	A transition on WAIT0 input pin has not been detected
		W0	WAIT0EDGEDETECTIONSTATUS bit unchanged
		R1	A transition on WAIT0 input pin has been detected
		W1	WAIT0EDGEDETECTIONSTATUS bit is reset
7-2	Reserved	0	Reserved
1	TERMINALCOUNTSTATUS		Status of the TerminalCountEvent interrupt
		R0	Indicates that CountValue is greater than 0
		W0	TERMINALCOUNTSTATUS bit unchanged
		R1	Indicates that CountValue is equal to 0
		W1	TERMINALCOUNTSTATUS bit is reset
0	FIFOEVENTSTATUS		Status of the FIFOEvent interrupt
		R0	Indicates than less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode.
		W0	FIFOEVENTSTATUS bit unchanged
		R1	Indicates than at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode.
		W1	FIFOEVENTSTATUS bit is reset

6.2 OCMC-RAM

6.2.1 Introduction

6.2.1.1 OCMC RAM Features

The on-chip memory controller consists of two separate modules that are OCP to ACE wrappers for ACE memories. The first wrapper is for a ROM; the second is for a RAM. Each wrapper has its own dedicated interface to the L3 interconnect. This device uses only the RAM wrapper which supports both BRGS single port and GLG single port CRAM.

- 32- or 64-bit width
- Initial latency max 2 cycles (due to OCP to memory core wrapper).
- Multiple memory bank control based on address MSBs
- Full OCP IP 2.0 Burst support. No wait state.

6.2.1.2 Unsupported OCMC RAM Features

For this device, the OCMC RAM implementation does not support parity.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.2.2 Integration

This device includes a single instantiation of the on-chip memory controller interfacing to a single 64-K bank of RAM.

Figure 6-88. OCMC RAM Integration

6.2.2.1 OCMC RAM Connectivity Attributes

The general connectivity attributes for the OCMC RAM modules are summarized in Table 6-96.

Table 6-96. OCMC RAM Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	None
DMA Requests	None
Physical Address	L3 Fast slave port

6.2.2.2 OCMC RAM Clock and Reset Management

The OCMC module uses a single clock for the module and its OCP interface.

Table 6-97. OCMC RAM Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_ocmc_clock Interface / Functional clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM

6.2.2.3 OCMC RAM Pin List

The OCMC RAM module does not include any external interface pins.

6.3 EMIF

6.3.1 Introduction

6.3.1.1 Features

The general features of the EMIF module are as follows:

- 16-bit and 32-bit data path to external SDRAM memory
  - Unused DID Data Macros disabled in 16-bit mode
- One 128-bit OCPIP 2.2 interface
- Support for the following memory types:
  - MDDR (LPDDR1)
  - DDR2
  - DDR3 (stretch goal)

External memory configurations supported:

- Memory device capacity
  - 64Mb, 128Mb, 256Mb, 512Mb, 1Gb and 2Gb devices support
- Flexible bank/row/column/chip-select address multiplexing schemes
- Support for 2 independent chip select, with their corresponding register sets, and independent page tracking
- Device driver strength feature for mobile DDR supported
- Supports following CAS latencies:
  - DDR2 => 2, 3, 4, 5, 6, and 7
  - DDR3 => 5, 6, 7, 8, 9, 10, and 11
  - mDDR => 2, 3, and 4
- Supports following number of internal banks:
  - DDR2 => 1, 2, 4, and 8
  - DDR3 => 1, 2, 4, and 8
  - mDDR => 1, 2, and 4
- Supports 256, 512, 1024, and 2048-word page sizes
- Supports burst length of 8 (sequential burst)
- Write/read leveling/calibration and data eye training in conjunction with GS70 DID
- Self Refresh and Power-Down modes for low power:
  - Flexible OCP to DDR address mapping to support Partial Array Self Refresh in LPDDR1, DDR2 and DDR3.
  - Temperature Controlled Self Refresh for LPDDR1 and DDR3 having on-chip temperature sensor.
- Periodic ZQ calibration for DDR3
- ODT on DDR2 and DDR3
- Prioritized refresh scheduling
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- SDRAM Data bus obfuscation for security without additional cycle latency
- Big and little endian modes

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.1.2 Unsupported EMIF Features

The following EMIF4DC module features are not supported in this device.

Table 6-98. Unsupported EMIF Features

Feature	Reason
32-bit data	Only 16 bits pinned out
Multiple DDR banks	Only 1 CS/ODT pinned out
DDR3	DDR3 is fully supported by the EMIF/Phy and pinout but achieving the required DDR3 minimum frequency is a stretch goal for the device.
DDR2 CAS Latency 2	Not supported by DID

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.2 Integration

6.3.2.1 EMIF Connectivity Attributes

The general connectivity attributes for the EMIF are shown in Table 6-99.

Table 6-99. EMIF Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3)GCLK (OCP) PD_PER_EMIF_GCLK (Func)
Reset Signals	USB_POR_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to Sabertooth
DMA Requests	None
Physical Address	L3 Fast Slave Port

6.3.2.2 EMIF Clock Management

The EMIF4 OCP interface (ocp_clk) is clocked by the L3 Fast clock sourced from the Core PLL. The DDR Command and Data macros are clocked by the DDR PLL. The PRCM divides this clock by two to create the EMIF functional clock (m_clk).

The OCP and functional clocks may be asynchronous because synchronization is managed in the EMIF4 internal FIFO (EMIF4 is set in asynchronous mode).

Table 6-100. EMIF Clock Signals

Clock Signal	Max Freq	Reference Source	Comments
ocp_clk (Interface clock)	200 Mhz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM
m_clk (EMIF functional clock)	100 Mhz	DDR PLL CLKOUT / 2	pd_per_emif_gclk From PRCM
cmd0_dfi_clk cmd1_dfi_clk cmd2_dfi_clk data0_dfi_clk data1_dfi_clk (Macro clocks)	200 MHz	DDR PLL CLKOUT	clkout_po From DDR PLL

6.3.2.3 EMIF Pin List

The EMIF/DDR external interface signals are shown in Table 6-101.

Table 6-101. EMIF Pin List

Pin	Type	Description
DDR_CK DDR_NCK	O	Differential clock pair
DDR_CKE	O	Clock enable
DDR_CSn0	O	Chip select
DDR_RASn	O	Row address strobe
DDR_CASn	O	Column address strobe

IODFT_CTRL_MISR_RSLT is shown in Figure 6-90 and described in Table 6-104.

Figure 6-90. IODFT_CTRL_MISR_RSLT Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-104. IODFT_CTRL_MISR_RSLT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	Reserved	R	0h	
25-16	reg_dqm_tlmr	R	0h	This contains the MISR result signature of a given test after the download function is executed. This result is for the DQM signals.
15-11	Reserved	R	0h	
10-0	reg_ctl_tlmr	R	0h	This contains the MISR result signature of a given test after the download function is executed. This result is for the control signals.

DRAFT ONLY

6.3.5.3 IODFT_ADDR_MISR_RSLT Register (offset = 68h)

IODFT_ADDR_MISR_RSLT is shown in Figure 6-91 and described in Table 6-105.

Figure 6-91. IODFT_ADDR_MISR_RSLT Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-105. IODFT_ADDR_MISR_RSLT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-21	Reserved	R	0h	
20-0	reg_addr_tlmr	R	0h	This contains the MISR result signature of a given test after the download function is executed. This result is for the address signals.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.4 IODFT_DATA_MISR_RSLT_1 Register (offset = 6Ch)

IODFT_DATA_MISR_RSLT_1 is shown in Figure 6-92 and described in Table 6-106.

Figure 6-92. IODFT_DATA_MISR_RSLT_1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-106. IODFT_DATA_MISR_RSLT_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	reg_data_tlmr_31_0	R	0h	This contains the least significant bits of the MISR result signature of a given test after the download function is executed. This result is for data bus.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.5 IODFT_DATA_MISR_RSLT_2 Register (offset = 70h)

IODFT_DATA_MISR_RSLT_2 is shown in Figure 6-93 and described in Table 6-107.

Figure 6-93. IODFT_DATA_MISR_RSLT_2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-107. IODFT_DATA_MISR_RSLT_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	reg_data_tlmr_63_32	R	0h	This contains the middle bits of the MISR result signature of a given test after the download function is executed. This result is for data bus.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.6 IODFT_DATA_MISR_RSLT_3 Register (offset = 74h)

IODFT_DATA_MISR_RSLT_3 is shown in Figure 6-94 and described in Table 6-108.

Figure 6-94. IODFT_DATA_MISR_RSLT_3 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-108. IODFT_DATA_MISR_RSLT_3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-3	Reserved	R	0h	
2-0	reg_data_tlmr_66_64	R	0h	This contains the most significant bits of the MISR result signature of a given test after the download function is executed. This result is for data bus.

6.3.5.7 SDRAM_CONFIG_2 Register (offset = Ch)

SDRAM_CONFIG_2 is shown in Figure 6-95 and described in Table 6-109.

Figure 6-95. SDRAM_CONFIG_2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-109. SDRAM_CONFIG_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	Reserved	R	0h	
30	reg_cs1nvmen	R/W	0h	CS1 LPDDR2-NVM enable. Set to 1 if LPDDR2-NVM is connected to CS1. This bit will automatically be set to 0 if reg_sdram_type field in the SDRAM Config register is not set to LPDDR2.
29-28	Reserved	R	0h	
27	reg_ebank_pos	R/W	0h	External bank position. Set to 0 to assign external bank address bits from lower OCP address as shown in tables. Set to 1 to assign external bank address bits from higher OCP address bits as shown in tables.
26-6	Reserved	R	0h	
5-4	reg_rdbnum	R/W	0h	Row Buffer setup. Defines number of row buffers inside connected LPDDR2-NVM devices. Set to 0 for 1 row buffer, set to 1 for 2 row buffers, set to 2 for 4 row buffers, and set to 3 for 8 row buffers. All other values are reserved.
3	Reserved	R	0h	
2-0	reg_rdbsize	R/W	0h	Row Data Buffer Size. Defines the row data buffer size of connected LPDDR2-NVM devices. Set to 0 for 32 bytes, set to 1 for 64 bytes, set to 2 for 128 bytes, set to 3 for 256 bytes, set to 4 for 512 bytes, set to 5 for 1024 bytes, set to 6 for 2048 bytes, and set to 7 for 4096 bytes.

6.3.5.8 PERF_CNT_1 Register (offset = 80h)

PERF_CNT_1 is shown in Figure 6-96 and described in Table 6-110.

Figure 6-96. PERF_CNT_1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-110. PERF_CNT_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	reg_counter1	R	0h	32-bit counter that can be configured as specified in the Performance Counter Config Register and Performance Counter Master Region Select Register.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.9 PERF_CNT_2 Register (offset = 84h)

PERF_CNT_2 is shown in Figure 6-97 and described in Table 6-111.

Figure 6-97. PERF_CNT_2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-111. PERF_CNT_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	reg_counter2	R	0h	32-bit counter that can be configured as specified in the Performance Counter Config Register and Performance Counter Master Region Select Register.

6.3.5.10 PERF_CNT_CFG Register (offset = 88h)

PERF_CNT_CFG is shown in Figure 6-98 and described in Table 6-112.

Figure 6-98. PERF_CNT_CFG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-112. PERF_CNT_CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_cntr2_mconnid_en	R/W	0h	MConnID filter enable for Performance Counter 2 register.
30	reg_cntr2_region_en	R/W	0h	Chip Select filter enable for Performance Counter 2 register.
29-20	Reserved	R	0h	
19-16	reg_cntr2_cfg	R/W	0h	Filter configuration for Performance Counter 2. Refer to table for details.
15	reg_cntr1_mconnid_en	R/W	0h	MConnID filter enable for Performance Counter 1 register.
14	reg_cntr1_region_en	R/W	0h	Chip Select filter enable for Performance Counter 1 register.
13-4	Reserved	R	0h	
3-0	reg_cntr1_cfg	R/W	0h	Filter configuration for Performance Counter 1. Refer to table for details.

6.3.5.11 PERF_CNT_SEL Register (offset = 8Ch)

PERF_CNT_SEL is shown in Figure 6-99 and described in Table 6-113.

Figure 6-99. PERF_CNT_SEL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-113. PERF_CNT_SEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	reg_mconnid2	R/W	0h	MConnID for Performance Counter 2 register.
23-18	Reserved	R	0h	
17-16	reg_region_sel2	R/W	0h	MAddrSpace for Performance Counter 2 register.
15-8	reg_mconnid1	R/W	0h	MConnID for Performance Counter 1 register.
7-2	Reserved	R	0h	
1-0	reg_region_sel1	R/W	0h	MAddrSpace for Performance Counter 1 register.

DRAFT ONLY

6.3.5.12 PERF_CNT_TIM Register (offset = 90h)

PERF_CNT_TIM is shown in Figure 6-100 and described in Table 6-114.

Figure 6-100. PERF_CNT_TIM Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-114. PERF_CNT_TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	reg_total_time	R	0h	32-bit counter that continuously counts number for m_clk cycles elapsed after EMIF is brought out of reset.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.13 READ_IDLE_CTRL Register (offset = 98h)

READ_IDLE_CTRL is shown in Figure 6-101 and described in Table 6-115.

Figure 6-101. READ_IDLE_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-115. READ_IDLE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	Reserved	R	0h	
19-16	reg_read_idle_len	R/W	4h	The Read Idle Length field determines the minimum size (reg_read_idle_len-1 clock cycles) of Read Idle window for the read idle detection as well as the force read idle time.
15-9	Reserved	R	0h	
8-0	reg_read_idle_interval	R/W	0h	The Read Idle Interval field determines the maximum interval ((reg_read_idle_interval-1)*64 clock cycles) between read idle detections or force. A value of zero disables the read idle function.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.14 READ_IDLE_CTRL_SHDW Register (offset = 9Ch)

READ_IDLE_CTRL_SHDW is shown in Figure 6-102 and described in Table 6-116.

Figure 6-102. READ_IDLE_CTRL_SHDW Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-116. READ_IDLE_CTRL_SHDW Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	Reserved	R	0h	
19-16	reg_read_idle_len_shdw	R/W	4h	Shadow field for reg_read_idle_len. This field is loaded into reg_read_idle_len field in Read Idle Control register when SIdleAck is asserted;
15-9	Reserved	R	0h	
8-0	reg_read_idle_interval_shdw	R/W	0h	Shadow field for reg_read_idle_interval. This field is loaded into reg_read_idle_interval field in Read Idle Control register when SIdleAck is asserted.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.3.5.15 SDRAM_REF_CTRL Register (offset = 10h)

SDRAM_REF_CTRL is shown in Figure 6-103 and described in Table 6-117.

Figure 6-103. SDRAM_REF_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 6-117. SDRAM_REF_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_initref_dis	R/W	0h	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.
30	Reserved	R	0h	
29	reg_srt	R/W	0h	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the reg_asr field is set to 0. This bit must be set to 0 if the reg_asr field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
28	reg_asr	R/W	0h	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the reg_srt field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
27	Reserved	R	0h	
26-24	reg_pasr	R/W	0h	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of an LPDDR1 or DDR3 during initialization. For LPDDR1, set to 0 for full array, set to 1 for 1/2 array, set to 2 for 1/4 array, set to 5 for 1/8 array, and set to 6 for 1/16 array to be refreshed. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
23-16	Reserved	R	0h	
15-0	reg_refresh_rate	R/W	0h	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = EMIF rate / reg_refresh_rate where EMIF rate is equal to m_clk rate. If reg_refresh_rate andlt; (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20 then it will be loaded with (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20. This is done to avoid lock-up situations when illegal values are programmed.

6.3.5.16 IRQ_EOI Register (offset = A0h)

IRQ_EOI is shown in Figure 11-58 and described in Table 11-59.

Figure 6-104. IRQ_EOI Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-118. IRQ_EOI Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	reg_eoi	R/W	0h	Software End Of Interrupt (EOI) control. Write 0 for system OCP interrupt and write 1 for low-latency OCP interrupt. This field always reads 0 (no EOI memory).

6.3.5.26 ZQ_CONFIG Register (offset = C8h)

ZQ_CONFIG is shown in Figure 6-114 and described in Table 6-128.

Figure 6-114. ZQ_CONFIG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-128. ZQ_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_zq_cs1en	R/W	0h	Writing a 1 enables ZQ calibration for CS1.
30	reg_zq_cs0en	R/W	0h	Writing a 1 enables ZQ calibration for CS0.
29	reg_zq_dualcalen	R/W	0h	ZQ Dual Calibration enable. Allows both ranks to be ZQ calibrated simultaneously. Setting this bit requires both chip selects to have a seerate calibration resistor per device.
28	reg_zq_sfexiten	R/W	0h	ZQCL on Self Refresh, Active Power-Down, and Precharge Power-Down exit enable. Writing a 1 enables the issuing of ZQCL on Self-Refresh, Active Power-Down, and Precharge Power-Down exit.
27-20	Reserved	R	0h	
19-18	reg_zq_zqinit_mult	R/W	0h	Indicates the number of ZQCL intervals that make up a ZQINIT interval, minus one.
17-16	reg_zq_zqcl_mult	R/W	0h	Indicates the number of ZQCS intervals that make up a ZQCL interval, minus one. ZQCS interval is defined by reg_zq_zqcs in SDRAM Timing 3 Register.
15-0	reg_zq_refinterval	R/W	0h	Number of refresh periods between ZQCS commans. This field supports between one refresh period to 256 ms between ZQCS calibration commands. Refresh period is defined by reg_refresh_rate in SDRAM Refresh Control register.

6.3.5.27 TEMP_ALERT_CONFIG Register (offset = CCh)

TEMP_ALERT_CONFIG is shown in Figure 6-115 and described in Table 6-129.

Figure 6-115. TEMP_ALERT_CONFIG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-129. TEMP_ALERT_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_ta_cs1en	R/W	0h	Writing a 1 enables temperature alert polling for CS1.
30	reg_ta_cs0en	R/W	0h	Writing a 1 enables temperature alert polling for CS0.
29	Reserved	R	0h	
28	reg_ta_sfexiten	R/W	0h	Temperature Alert Poll on Self-Refresh, Active Power-Down, and Precharge Power-Down exit enable. Writing a 1 enables the issuing of a temperature alert poll on Self-Refresh exit.
27-26	reg_ta_devwdt	R/W	0h	
25-24	reg_ta_devcnt	R/W	0h	
23-22	Reserved	R	0h	
21-0	reg_ta_refinterval	R/W	0h	Number of refresh periods between temperature alert polls. This field supports one refresh period to 10 seconds between temperature alert polls. Refresh period is defined by reg_refresh_rate in SDRAM Refresh Control register.

6.3.5.28 OCP_ERR_LOG Register (offset = D0h)

OCP_ERR_LOG is shown in Figure 6-116 and described in Table 6-130.

Figure 6-116. OCP_ERR_LOG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 6-130. OCP_ERR_LOG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	Reserved	R	0h	
15-14	reg_MAddrSpace	R	0h	Address space of the first errored transaction. Writing a 1 to the It field in the Interrupt Raw register or the It_masked field in the Interrupt Masked register will clear this field.
13-11	reg_MBurstSeq	R	0h	Addressing mode of the first errored transaction. Writing a 1 to the It field in the Interrupt Raw register or the It_masked field in the Interrupt Masked register will clear this field.
10-8	reg_MCmd	R	0h	Command type of the first errored transaction. Writing a 1 to the It field in the Interrupt Raw register or the It_masked field in the Interrupt Masked register will clear this field.
7-0	reg_MConnID	R	0h	Connection ID of the first errored transaction. Writing a 1 to the It field in the Interrupt Raw register or the It_masked field in the Interrupt Masked register will clear this field.

6.3.5.29 DDR_PHY_CTRL_1 Register (offset = E4h)

DDR_PHY_CTRL_1 is shown in Figure 6-117 and described in Table 6-131.

Figure 6-117. DDR_PHY_CTRL_1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-131. DDR_PHY_CTRL_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	reg_ddr_phy_ctrl_1	R/W	0h	This register is used to control the DDR PHY. The bit field definitions are DDR PHY specific and should be described in the DDR PHY specification.
3-0	reg_read_latency	R/W	0h	This field defines the read latency for the read data from SDRAM in number of m_clk cycles. This field is used by the EMIF as well as the PHY. The EMIF will expect the first read data to arrive (reg_read_latency + 3) m_clk cycles from the read command. Refer to the PHY specification for information on programming this field.

6.3.5.32 SDRAM_TIM_1 Register (offset = 18h)

SDRAM_TIM_1 is shown in Figure 6-120 and described in Table 6-134.

Figure 6-120. SDRAM_TIM_1 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-134. SDRAM_TIM_1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	Reserved	R	0h	
28-25	reg_t_rp	R/W	0h	Minimum number of m_clk cycles from Precharge to Activate or Refresh, minus one.
24-21	reg_t_rcd	R/W	0h	Minimum number of m_clk cycles from Activate to Read or Write, minus one.
20-17	reg_t_wr	R/W	0h	Minimum number of m_clk cycles from last Write transfer to Pre-charge, minus one. The SDRAM initialization sequence will be started when the value of this field is changed from the previous value and the EMIF is in DDR2 mode.
16-12	reg_t_ras	R/W	0h	Minimum number of m_clk cycles from Activate to Pre-charge, minus one. reg_t_ras >= reg_t_rcd.
11-6	reg_t_rc	R/W	0h	Minimum number of m_clk cycles from Activate to Activate, minus one.
5-3	reg_t_rrd	R/W	0h	Minimum number of m_clk cycles from Activate to Activate for a different bank, minus one. For an 8-bank DDR2, this field must be equal to ((((4*tRRD)+(2*tCK))/(4*tCK))-1).
2-0	reg_t_wtr	R/W	0h	Minimum number of m_clk cycles from last Write to Read, minus one.

6.3.5.33 SDRAM_TIM_1_SHDW Register (offset = 1Ch)

SDRAM_TIM_1_SHDW is shown in Figure 6-121 and described in Table 6-135.

Figure 6-121. SDRAM_TIM_1_SHDW Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-135. SDRAM_TIM_1_SHDW Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	Reserved	R	0h	
28-25	reg_t_rp_shdw	R/W	0h	Shadow field for reg_t_rp. This field is loaded into reg_t_rp field in SDRAM Timing 1 register when SIdleAck is asserted.
24-21	reg_t_rcd_shdw	R/W	0h	Shadow field for reg_t_rcd. This field is loaded into reg_t_rcd field in SDRAM Timing 1 register when SIdleAck is asserted.
20-17	reg_t_wr_shdw	R/W	0h	Shadow field for reg_t_wr. This field is loaded into reg_t_wr field in SDRAM Timing 1 register when SIdleAck is asserted. initialization sequence will be started when the value of this field is changed from the previous value and the EMIF is in DDR2 mode.
16-12	reg_t_ras_shdw	R/W	0h	Shadow field for reg_t_ras. This field is loaded into reg_t_ras field in SDRAM Timing 1 register when SIdleAck is asserted.
11-6	reg_t_rc_shdw	R/W	0h	Shadow field for reg_t_rc. This field is loaded into reg_t_rc field in SDRAM Timing 1 register when SIdleAck is asserted.
5-3	reg_t_rrd_shdw	R/W	0h	Shadow field for reg_t_rrd. This field is loaded into reg_t_rrd field in SDRAM Timing 1 register when SIdleAck is asserted.
2-0	reg_t_wtr_shdw	R/W	0h	Shadow field for reg_t_wtr. This field is loaded into reg_t_wtr field in SDRAM Timing 1 register when SIdleAck is asserted.

6.3.5.34 SDRAM_TIM_2 Register (offset = 20h)

SDRAM_TIM_2 is shown in Figure 6-122 and described in Table 6-136.

Figure 6-122. SDRAM_TIM_2 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-136. SDRAM_TIM_2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	Reserved	R	0h	
30-28	reg_t_xp	R/W	0h	Minimum number of m_clk cycles from Powerdown exit to any command other than a Read command, minus one. For DDR2 and LPDDR1, this field must satisfy greater of tXP or tCKE.
27-25	reg_t_odt	R/W	0h	Minimum number of m_clk cycles from ODT enable to write data driven for DDR2 and DDR3. reg_t_odt must be equal to tAOND.
24-16	reg_t_xsnr	R/W	0h	Minimum number of m_clk cycles from Self-Refresh exit to any command other than a Read command, minus one.
15-6	reg_t_xsrd	R/W	0h	Minimum number of m_clk cycles from Self-Refresh exit to a Read command, minus one.
5-3	reg_t_rtp	R/W	0h	Minimum number of m_clk cycles from the last Read command to a Pre-charge command for DDR2, minus one.
2-0	reg_t_cke	R/W	0h	Minimum number of m_clk cycles between pad_cke_o changes, minus one.

6.3.5.35 SDRAM_TIM_2_SHDW Register (offset = 24h)

SDRAM_TIM_2_SHDW is shown in Figure 6-123 and described in Table 6-137.

Figure 6-123. SDRAM_TIM_2_SHDW Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-137. SDRAM_TIM_2_SHDW Register Field Descriptions

Bit	Field	Type	Reset	Description
31	Reserved	R	0h	
30-28	reg_t_xp_shdw	R/W	0h	Shadow field for reg_t_xp. This field is loaded into reg_t_xp field in SDRAM Timing 2 register when SIdleAck is asserted.
27-25	reg_t_odt_shdw	R/W	0h	Shadow field for reg_t_odt. This field is loaded into reg_t_odt field in SDRAM Timing 2 register when SIdleAck is asserted.
24-16	reg_t_xsnr_shdw	R/W	0h	Shadow field for reg_t_xsnr. This field is loaded into reg_t_xsnr field in SDRAM Timing 2 register when SIdleAck is asserted.
15-6	reg_t_xsrd_shdw	R/W	0h	Shadow field for reg_t_xsrd. This field is loaded into reg_t_xsrd field in SDRAM Timing 2 register when SIdleAck is asserted.
5-3	reg_t_rtp_shdw	R/W	0h	Shadow field for reg_t_rtp. This field is loaded into reg_t_rtp field in SDRAM Timing 2 register when SIdleAck is asserted.
2-0	reg_t_cke_shdw	R/W	0h	Shadow field for reg_t_cke. This field is loaded into reg_t_cke field in SDRAM Timing 2 register when SIdleAck is asserted.

6.3.5.36 STATUS Register (offset = 4h)

STATUS is shown in Figure 6-124 and described in Table 6-138.

Figure 6-124. STATUS Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-138. STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_be	R	0h	Big Endian. Reflects the value on the config_big_endian port that defines whether the EMIF is in big or little endian mode.
30	reg_dual_clk_mode	R	0h	Dual Clock mode. Reflects the value on the config_dual_clk_mode port that defines whether the ocp_clk and m_clk are asynchronous.
29	reg_fast_init	R	0h	Fast Init. Reflects the value on the config_fast_init port that defines whether the EMIF fast initialization mode has been enabled.
28-3	Reserved	R	0h	
2	reg_phy_dll_ready	R	0h	DDR PHY Ready. Reflects the value on the phy_ready port (active high) that defines whether the DDR PHY is ready for normal operation.
1-0	Reserved	R	0h

6.3.5.37 SDRAM_TIM_3 Register (offset = 28h)

SDRAM_TIM_3 is shown in Figure 6-125 and described in Table 6-139.

Figure 6-125. SDRAM_TIM_3 Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-139. SDRAM_TIM_3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	Reserved	R	0h	
23-21	reg_t_ckesr	R/W	0h	Minimum number of m_clk cycles for which LPDDR2 must remain in Self Refresh, minus one.
20-15	reg_zq_zqcs	R/W	0h	Number of m_clk clock cycles for a ZQCS command, minus one.
14-13	reg_t_tdqsckmax	R/W	0h	Number of m_clk that satisfies tDQSCKmax for LPDDR2, minus one.
12-4	reg_t_rfc	R/W	0h	Minimum number of m_clk cycles from Refresh or Load Mode to Refresh or Activate, minus one.
3-0	reg_t_ras_max	R/W	0h	Maximum number of reg_refresh_rate intervals from Activate to Precharge command. This field must be equal to ((tRASmax / tREFI)-1) rounded down to the next lower integer.

6.3.5.41 PWR_MGMT_CTRL Register (offset = 38h)

PWR_MGMT_CTRL is shown in Figure 6-129 and described in Table 6-143.

Figure 6-129. PWR_MGMT_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-143. PWR_MGMT_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	Reserved	R	0h	
15-12	reg_pd_tim	R/W	0h	Power Mangement timer for Power-Down. The EMIF will put the external SDRAM in Power-Down mode after the EMIF is idle for these number of m_clk cycles and if reg_lp_mode field is set to 4. Set to 0 to immediately enter Power-Down mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.
11	reg_dpd_en	R/W	0h	Deep Power Down enable. Set to 0 for normal operation. Set to 1 to enter deep power down mode. This mode will override the reg_lp_mode field setting.
10-8	reg_lp_mode	R/W	0h	Automatic Power Management enable. Set to 1 for Clock Stop, set to 2 for Self Refresh, and set to 4 for Power-Down. All other values will disable automatic power management.
7-4	reg_sr_tim	R/W	0h	Power Mangement timer for Self Refresh. The EMIF will put the external SDRAM in Self Refresh mode after the EMIF is idle for these number of m_clk cycles and if reg_lp_mode field is set to 2. Set to 0 to immediately enter Self Refresh mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.
3-0	reg_cs_tim	R/W	0h	Power Mangement timer for Clock Stop. The EMIF will put the external SDRAM in Clock Stop mode after the EMIF is idle for these number of m_clk cycles and if reg_lp_mode field is set to 1. Set to 0 to immediately enter Clock Stop mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.

6.3.5.44 SDRAM_CONFIG Register (offset = 8h)

SDRAM_CONFIG is shown in Figure 6-132 and described in Table 6-146.

Figure 6-132. SDRAM_CONFIG Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 6-146. SDRAM_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	reg_sdram_type	R/W	0h	SDRAM Type selection. Set to 0 for DDR1, set to 1 for LPDDR1, set to 2 for DDR2, set to 3 for DDR3, and set to 4 for LPDDR2. All other values are reserved.
28-27	reg_ibank_pos	R/W	0h	Internal bank position. Set to 0 to assign internal bank address bits from lower OCP address bits as shown in tables. Set to 1, 2, or 3 to assign internal bank address bits from higher OCP address as shown in tables.
26-24	reg_ddr_term	R/W	0h	DDR2 and DDR3 termination resistor value. Set to 0 to disable termination. For DDR2, set to 1 for 75 ohm, set to 2 for 150 ohm, and set to 3 for 50 ohm. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.
23	reg_ddr2_ddqs	R/W	0h	DDR2 and LPDDR2 differential DQS enable. Set to 0 for single ended DQS. Set to 1 for differential DQS.
22-21	reg_dyn_odt	R/W	0h	DDR3 Dynamic ODT. Set to 0 to turn off dynamic ODT. Set to 1 for RZQ/4 and set to 2 for RZQ/2. All other values are reserved.
20	reg_ddr_disable_dll	R/W	0h	Disable DLL select. Set to 1 to disable DLL inside SDRAM.
19-18	reg_sdram_drive	R/W	0h	SDRAM drive strength. For DDR1/DDR2, set to 0 for normal, and set to 1 for weak drive strength. For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. For LPDDR1, set to 0 for full, set to 1 for 1/2, set to 2 for 1/4, and set to 3 for 1/8 drive strength. All other values are reserved.
17-16	reg_cwl	R/W	0h	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.
15-14	reg_narrow_mode	R/W	0h	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved.
13-10	reg_cl	R/W	0h	CAS Latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 2, 3, 5, and 6 (CAS latency of 2, 3, 1.5, and 2.5) are supported for DDR1. Value of 2, 3, 4, and 5 (CAS latency of 2, 3, 4, and 5) are supported for DDR2. Value of 2, 4, 6, 8, 10, 12, and 14 (CAS latency of 5, 6, 7, 8, 9, 10, and 11) are supported for DDR3. Value of 2 and 3 (CAS latency of 2 and 3) are supported for LPDDR1. Value of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. All other values are reserved.
9-7	reg_rowsize	R/W	0h	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, set to 1 for 10 row bits, set to 2 for 11 row bits, set to 3 for 12 row bits, set to 4 for 13 row bits, set to 5 for 14 row bits, set to 6 for 15 row bits, and set to 7 for 16 row bits. This field is only used when reg_ibank_pos field in SDRAM Config register is set to 1, 2, or 3, or reg_ebank_pos field in SDRAM Config_2 register is set to 1."
6-4	reg_ibank	R/W	0h	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, set to 1 for 2 banks, set to 2 for 4 banks, and set to 3 for 8 banks. All other values are reserved.
3	reg_ebank	R/W	0h	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0]. This bit will automaticlly be set to 0 if reg_cs1nvmen field in the LPDDR2-NVM is set to 1.

6.4 ELM

6.4.1 Introduction

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as bare NANDs, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as uncorrectable in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

6.4.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

6.4.1.2 Unsupported ELM Features

There are no unsupported ELM features in this device.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.4.2 Integration

The error location module (ELM) is used to extract error addresses from syndrome polynomials generated using a BCH algorithm. Each of these polynomials gives a status of the read operations for a 512 bytes block from a NAND flash and its associated BCH parity bits, plus optionally some spare area information.

The ELM is intended to be used in conjunction with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND Flash page and stored in GPMC registers are passed to the ELM module. The MPU can then easily correct the data block by flipping the bits pointed to by the ELM error locations outputs.

6.4.2.1 ELM Connectivity Attributes

The general connectivity for the ELM module in this device is summarized in Table 6-152.

Table 6-152. ELM Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to Sabertooth
DMA Requests	None
Physical Address	L4 Peripheral slave port

6.4.2.2 ELM Clock and Reset Management

The ELM operates from a single OCP interface clock.

Table 6-153. ELM Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Functional/interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

6.4.2.3 ELM Pin List

The ELM module does not include any external interface pins.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

6.4.3 Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

6.4.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

6.4.3.2 ELM Power Management

Table 6-154 describes the power-management features available to the ELM module.

Table 6-154. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

6.4.3.3 ELM Interrupt Requests

Table 6-155 lists the event flags, and their masks, that can cause module interrupts.

Table 6-155. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2

DRAFT ONLY

Table 6-155. Events (continued)

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

6.4.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

6.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 6-156. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

6.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

Table 6-158. ELM Processing Completion for Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 6-159. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

6.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 6-160. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2

Table 6-160. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 6-161 are given in decimal format.

260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

6.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

7.1.5.1.1 PM_CEFUSE_PWRSTCTRL Register (offset = 0h)

This register controls the CEFUSE power state to reach upon a domain sleep transition

PM_CEFUSE_PWRSTCTRL is shown in Figure 7-1 and described in Table 7-2.

Figure 7-1. PM_CEFUSE_PWRSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-2. PM_CEFUSE_PWRSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	Reserved	R	0h	
4	LowPowerStateChange	R/W	0h	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0 - DIS: Do not request a low power state change. 1 - EN: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.
3-2	Reserved	R	0h	
1-0	PowerState	R/W	0h	Power state control 0 - OFF: OFF state 1 - Reserved: Reserved 2 - INACT: INACTIVE state 3 - ON: ON State

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

7.1.5.1.2 PM_CEFUSE_PWRSTST Register (offset = 4h)

This register provides a status on the current CEFUSE power domain state. [warm reset insensitive]

PM_CEFUSE_PWRSTST is shown in Figure 7-2 and described in Table 7-3.

Figure 7-2. PM_CEFUSE_PWRSTST Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-3. PM_CEFUSE_PWRSTST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	Reserved	R	0h	
25-24	LastPowerStateEntered	R/W	0h	Last low power state entered. Set to 0x3 upon write of the same only. This register is intended for debug purpose only. 0 - OFF: Power domain was previously OFF 1 - ON: Power domain was previously ON-ACTIVE
23-21	Reserved	R	0h	
20	InTransition	R	0h	Domain transition status 0 - No: No on-going transition on power domain 1 - Ongoing: Power domain transition is in progress.
19-3	Reserved	R	0h	
2	LogicStateSt	R	1h	Logic state status 0 - OFF: Logic in domain is OFF 1 - ON: Logic in domain is ON
1-0	PowerStateSt	R	3h	Current power state status 0 - OFF: Power domain is OFF 1 - RET: Power domain is in RETENTION 2 - INACTIVE: Power domain is ON-INACTIVE 3 - ON: Power domain is ON-ACTIVE

7.1.5.2 PRM_DEVICE Registers

Table 7-4 lists the memory-mapped registers for the PRM_DEVICE. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 7-4 should be considered as reserved locations and the register contents should not be modified.

Table 7-4. PRM_DEVICE REGISTERS

Offset	Acronym	Register Description	Section
0h	PRM_RSTCTRL	Global software cold and warm reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.	Section 7.1.5.2.1
Ch	PRM_SRAM_COUNT	Common setup for SRAM LDO transition counters. Applies to all voltage domains. [warm reset insensitive]	Section 7.1.5.2.2
10h	PRM_LDO_SRAM_CORE_SETUP	Setup of the SRAM LDO for CORE voltage domain. [warm reset insensitive]	Section 7.1.5.2.3
14h	PRM_LDO_SRAM_CORE_CTRL	Control and status of the SRAM LDO for CORE voltage domain. [warm reset insensitive]	Section 7.1.5.2.4
18h	PRM_LDO_SRAM_MPU_SETUP	Setup of the SRAM LDO for MPU voltage domain. [warm reset insensitive]	Section 7.1.5.2.5
1Ch	PRM_LDO_SRAM_MPU_CTRL	Control and status of the SRAM LDO for MPU voltage domain. [warm reset insensitive]	Section 7.1.5.2.6
4h	PRM_RSTTIME	Reset duration control. [warm reset insensitive]	Section 7.1.5.2.7
8h	PRM_RSTST	This register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]	Section 7.1.5.2.8

7.1.5.2.1 PRM_RSTCTRL Register (offset = 0h)

Global software cold and warm reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.

PRM_RSTCTRL is shown in Figure 7-3 and described in Table 7-5.

Figure 7-3. PRM_RSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-5. PRM_RSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0h	
1	RST_GLOBAL_COLD_SW	R/W	0h	Global COLD software reset control. This bit is reset only upon a global cold source of reset. 0 - 0x0: Global COLD software reset is cleared. 1 - 0x1: Asserts a global COLD software reset. The software must ensure the SDRAM is properly put in sef-refresh mode before applying this reset.
0	RST_GLOBAL_WARM_SW	R/W	0h	Global WARM software reset control. This bit is reset upon any global source of reset (warm and cold). 0 - 0x0: Global warm software reset is cleared. 1 - 0x1: Asserts a global warm software reset.

7.1.5.2.2 PRM_SRAM_COUNT Register (offset = Ch)

Common setup for SRAM LDO transition counters. Applies to all voltage domains. [warm reset insensitive]

PRM_SRAM_COUNT is shown in Figure 7-4 and described in Table 7-6.

Figure 7-4. PRM_SRAM_COUNT Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-6. PRM_SRAM_COUNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	StartUp_Count	R/W	78h	Determines the start-up duration of SRAM and ABB LDO. The duration is computed as 16 x NbCycles of system clock cycles. Target is 50us.
23-16	SLPCNT_VALUE	R/W	0h	Delay between retention/off assertion of last SRAM bank and SRAMALLRET signal to LDO is driven high. Counting on system clock. Target is 2us.
15-8	VSETUPCNT_VALUE	R/W	0h	SRAM LDO rampup time from retention to active mode. The duration is computed as 8 x NbCycles of system clock cycles. Target is 30us.
7-6	Reserved	R	0h	
5-0	PCHARGECNT_VALUE	R/W	17h	Delay between de-assertion of standby_rta_ret_on and standby_rta_ret_good. Counting on system clock. Target is 600ns.

DRAFT ONLY

7.1.5.2.3 PRM_LDO_SRAM_CORE_SETUP Register (offset = 10h)

Setup of the SRAM LDO for CORE voltage domain. [warm reset insensitive]

PRM_LDO_SRAM_CORE_SETUP is shown in Figure 7-5 and described in Table 7-7.

Figure 7-5. PRM_LDO_SRAM_CORE_SETUP Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-7. PRM_LDO_SRAM_CORE_SETUP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	Reserved	R	0h	
8	AIPOFF	R/W	0h	Override on AIPOFF input of SRAM LDO. 0 - No_Override: AIPOFF signal is not overriden 1 - Override: AIPOFF signal is overriden to '1'. Corresponding SRAM LDO is disabled and in HZ mode.
7	ENFUNC5	R/W	0h	ENFUNC5 input of SRAM LDO. 0 - One_step: Active to retention is a one step transfer 1 - Two_step: Active to retention is a two steps transfer
6	ENFUNC4	R/W	0h	ENFUNC4 input of SRAM LDO. 0 - Ext_clock: One external clock is supplied 1 - No_ext_clock: No external clock is supplied
5	ENFUNC3_EXPORT	R/W	0h	ENFUNC3 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - Sub_regul_disabled: Sub regulation is disabled 1 - Sub_regul_enabled: Sub regulation is enabled
4	ENFUNC2_EXPORT	R/W	0h	ENFUNC2 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - Ext_cap: External cap is used 1 - No_ext_cap: External cap is not used
3	ENFUNC1_EXPORT	R/W	0h	ENFUNC1 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - Short_prot_disabled: Short circuit protection is disabled 1 - Short_prot_enabled: Short circuit protection is enabled
2	ABBOFF_SLEEP_EXPORT	R/W	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during deep-sleep. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - SRAMNW_SLP_VDDS: SRAMNWA supplied with VDDS 1 - SRAMNW_SLP_VDDAR: SRAMNWA supplied with VDDAR
1	ABBOFF_ACT_EXPORT	R/W	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during active mode. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - SRAMNW_ACT_VDDS: SRAMNWA supplied with VDDS 1 - SRAMNW_ACT_VDDAR: SRAMNWA supplied with VDDAR
0	DISABLE_RTA_EXPORT	R/W	0h	Control for HD memory RTA feature. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0 - RTA_ENABLED: HD memory RTA feature is enabled 1 - RTA_DISABLED: HD memory RTA feature is disabled

7.1.5.2.4 PRM_LDO_SRAM_CORE_CTRL Register (offset = 14h)

Control and status of the SRAM LDO for CORE voltage domain. [warm reset insensitive]

PRM_LDO_SRAM_CORE_CTRL is shown in Figure 7-6 and described in Table 7-8.

Figure 7-6. PRM_LDO_SRAM_CORE_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-8. PRM_LDO_SRAM_CORE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	SRAM_IN_TRANSITION	R	0h	Status indicating SRAM LDO state machine state. 0 - IDLE: SRAM LDO state machine is stable 1 - IN_TRANSITION: SRAM LDO state machine is in transition state
8	SRAMLDO_STATUS	R	0h	SRAMLDO status 0 - ACTIVE: SRAMLDO is in ACTIVE mode. 1 - RETENTION: SRAMLDO is on RETENTION mode.
7-1	Reserved	R	0h	
0	RETMODE_ENABLE	R/W	0h	Control if the SRAM LDO retention mode is used or not. 0 - Disabled: SRAM LDO is not allowed to go to RET mode 1 - Enabled: SRAM LDO go to RET mode when all memory of voltage domain are OFF or RET

7.1.5.2.6 PRM_LDO_SRAM_MPU_CTRL Register (offset = 1Ch)

Control and status of the SRAM LDO for MPU voltage domain. [warm reset insensitive]

PRM_LDO_SRAM_MPU_CTRL is shown in Figure 7-8 and described in Table 7-10.

Figure 7-8. PRM_LDO_SRAM_MPU_CTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-10. PRM_LDO_SRAM_MPU_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	SRAM_IN_TRANSITION	R	0h	Status indicating SRAM LDO state machine state. 0 - IDLE: SRAM LDO state machine is stable 1 - IN_TRANSITION: SRAM LDO state machine is in transition state
8	SRAMLDO_STATUS	R	0h	SRAMLDO status 0 - ACTIVE: SRAMLDO is in ACTIVE mode. 1 - RETENTION: SRAMLDO is on RETENTION mode.
7-1	Reserved	R	0h	
0	RETMODE_ENABLE	R/W	0h	Control if the SRAM LDO retention mode is used or not. 0 - Disabled: SRAM LDO is not allowed to go to RET mode 1 - Enabled: SRAM LDO go to RET mode when all memory of voltage domain are OFF or RET

7.1.5.2.8 PRM_RSTST Register (offset = 8h)

This register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

PRM_RSTST is shown in Figure 7-10 and described in Table 7-12.

Figure 7-10. PRM_RSTST Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-12. PRM_RSTST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	ICEPICK_RST	R/W	0h	IcePick reset event. This is a source of global warm reset initiated by the emulation. [warm reset insensitive] 0 - 0x0: No ICEPICK reset. 1 - 0x1: IcePick reset has occurred.
8-6	Reserved	R	0h	
5	EXTERNAL_WARM_RST	R/W	0h	External warm reset event [warm reset insensitive] 0 - 0x0: No global warm reset. 1 - 0x1: Global external warm reset has occurred.
4	WDT1_RST	R/W	0h	Watchdog1 timer reset event. This is a source of global WARM reset. [warm reset insensitive] 0 - 0x0: No watchdog reset. 1 - 0x1: watchdog reset has occurred.
3	WDT0_RST	R/W	0h	Watchdog0 timer reset event. This is a source of global WARM reset. [warm reset insensitive] 0 - 0x0: No watchdog reset. 1 - 0x1: watchdog reset has occurred.
2	MPU_SECURITY_VIOL_RST	R/W	0h	Security violation reset event triggered by Security State Machine inside MPUSS. This is a source of global WARM reset. [warm reset insensitive] 0 - 0x0: No security violation reset. 1 - 0x1: Security violation reset has occurred.
1	GLOBAL_WARM_SW_RST	R/W	0h	Global warm software reset event [warm reset insensitive] 0 - 0x0: No global warm SW reset 1 - 0x1: Global warm SW reset has occurred.
0	GLOBAL_COLD_RST	R/W	1h	Power-on (cold) reset event [warm reset insensitive] 0 - 0x0: No power-on reset. 1 - 0x1: Power-on reset has occurred.

7.1.5.3.1 PM_MPU_PWRSTCTRL Register (offset = 0h)

This register controls the MPU power state to reach upon mpu domain sleep transition

PM_MPU_PWRSTCTRL is shown in Figure 7-11 and described in Table 7-14.

Figure 7-11. PM_MPU_PWRSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-14. PM_MPU_PWRSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	Reserved	R	0h	
25	Reserved	R	0h	
24	mpu_ram_RETState	R/W	1h	Default power domain memory(ram) retention state when power domain is in retention
23	mpu_l2_RETState	R/W	1h	Default power domain memory(L2) retention state when power domain is in retention
22	mpu_l1_RETState	R/W	1h	Default power domain memory(L1) retention state when power domain is in retention
21-20	MPU_L2_ONState	R	3h	Default power domain memory state when domain is ON. 3 - Mem_on: Memory bank is on when the domain is ON.
19-18	MPU_L1_ONState	R	3h	Default power domain memory state when domain is ON. 3 - Mem_on: Memory bank is on when the domain is ON.
17-16	MPU_RAM_ONState	R/W	3h	Default power domain memory state when domain is ON. 0 - Mem_off 2 - Reserved 3 - Mem_on: Memory bank is on when the domain is ON.
15-5	Reserved	R	0h	
4	LowPowerStateChange	R/W	0h	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0 - DIS: Do not request a low power state change. 1 - EN: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.
3	Reserved	R	0h	
2	LogicRETState	R/W	1h	Logic state when power domain is RETENTION 0 - logic_off: Only retention registers are retained and remaing logic is off when the domain is in RETENTION state. 1 - logic_ret: Whole logic is retained when domain is in RETENTION state.
1-0	PowerState	R/W	3h	Power state control 0 - OFF: OFF State 1 - RET 2 - Reserved 3 - ON: ON State

7.2.5.0.5.1 CM_CEFUSE_CLKSTCTRL Register (offset = 0h)

This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_CEFUSE_CLKSTCTRL is shown in Figure 7-24 and described in Table 7-31.

Figure 7-24. CM_CEFUSE_CLKSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-31. CM_CEFUSE_CLKSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	CLKACTIVITY_CUST_EFUSE_SYS_CLK	R	0h	This field indicates the state of the Cust_Efuse_SYSCLK clock input of the domain. [warm reset insensitive] 0 - Inact: Corresponding clock is definitely gated 1 - Act: Corresponding clock is running or gating/ungating transition is on-going
8	CLKACTIVITY_L4_CEFUSE_GICLK	R	0h	This field indicates the state of the L4_CEFUSE_GCLK clock input of the domain. [warm reset insensitive] 0 - Inact: Corresponding clock is definitely gated 1 - Act: Corresponding clock is running or gating/ungating transition is on-going
7-2	Reserved	R	0h	
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the clock domain in customer efuse power domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.5.2 CM_CEFUSE_CEFUSE_CLKCTRL Register (offset = 20h)

This register manages the CEFUSE clocks.

CM_CEFUSE_CEFUSE_CLKCTRL is shown in Figure 7-25 and described in Table 7-32.

Figure 7-25. CM_CEFUSE_CEFUSE_CLKCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-32. CM_CEFUSE_CEFUSE_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	Reserved	R	0h	
17-16	IDLEST	R	3h	Module idle status. [warm reset insensitive] 0 - Func: Module is fully functional, including OCP 1 - Trans: Module is performing transition: wakeup, or sleep, or sleep abortion 2 - Idle: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 - Disable: Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. 0 - DISABLED: Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 - RESERVED_1: Reserved 2 - ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 - RESERVED: Reserved

7.2.5.0.8.2 CM_GFX_L4LS_GFX_CLKSTCTRL Register (offset = Ch) [reset = 0h]

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_GFX_L4LS_GFX_CLKSTCTRL is shown in Figure 7-42 and described in Table 7-52.

Figure 7-42. CM_GFX_L4LS_GFX_CLKSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-52. CM_GFX_L4LS_GFX_CLKSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	Reserved	R	XXXh	
8	CLKACTIVITY_L4LS_GFX_GCLK	R	XXXh	This field indicates the state of the L4_LS clock in the domain. 0 - Inact 1 - Act
7-2	Reserved	R	XXXh	
1-0	CLKTRCTRL	R/W	XXXh	Controls the clock state transition of the L4LS clock domain in GFX power domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.8.3 CM_GFX_MMUCFG_CLKCTRL Register (offset = 10h) [reset = 0h]

This register manages the MMU CFG clocks.

CM_GFX_MMUCFG_CLKCTRL is shown in Figure 7-43 and described in Table 7-53.

Figure 7-43. CM_GFX_MMUCFG_CLKCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-53. CM_GFX_MMUCFG_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	Reserved	R	XXXh	
17-16	IDLEST	R	XXXh	Module idle status. 0 - Func: Module is fully functional, including OCP 1 - Trans: Module is performing transition: wakeup, or sleep, or sleep abortion 2 - Idle: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 - Disable: Module is disabled and cannot be accessed
15-2	Reserved	R	XXXh	
1-0	MODULEMODE	R/W	XXXh	Control the way mandatory clocks are managed. 0 - DISABLED: Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 - RESERVED_1: Reserved 2 - ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 - RESERVED: Reserved

Table 7-61. CM_PER_L4LS_CLKSTCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	CLKACTIVITY_GPIO_1_GDBCLK	R	1h	This field indicates the state of the GPIO1_GDBCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
18	CLKACTIVITY_GPIO_6_GDBCLK	R	1h	This field indicates the state of the GPIO6_GDBCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
17	CLKACTIVITY_LCDC_GCLK	R	0h	This field indicates the state of the LCD clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
16	CLKACTIVITY_TIMER4_GCLK	R	0h	This field indicates the state of the TIMER4 CLKTIMER clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
15	CLKACTIVITY_TIMER3_GCLK	R	0h	This field indicates the state of the TIMER3 CLKTIMER clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
14	CLKACTIVITY_TIMER2_GCLK	R	0h	This field indicates the state of the TIMER2 CLKTIMER clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
13	CLKACTIVITY_TIMER7_GCLK	R	0h	This field indicates the state of the TIMER7 CLKTIMER clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
12	Reserved	R	0h	
11	CLKACTIVITY_CAN_CLK	R	0h	This field indicates the state of the CAN_CLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
10	CLKACTIVITY_UART_GFCLK	R	0h	This field indicates the state of the UART_GFCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
9	Reserved	R	0h	
8	CLKACTIVITY_L4LS_GCLK	R	1h	This field indicates the state of the L4LS_GCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
7-2	Reserved	R	0h	
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the L4 SLOW clock domain in PER power domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.10.35 CM_PER_L3_INSTR_CLKCTRL Register (offset = DCh)

This register manages the L3 INSTR clocks.

CM_PER_L3_INSTR_CLKCTRL is shown in Figure 7-83 and described in Table 7-95.

Figure 7-83. CM_PER_L3_INSTR_CLKCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-95. CM_PER_L3_INSTR_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	Reserved	R	0h	
17-16	IDLEST	R	0h	Module idle status. 0 - Func: Module is fully functional, including OCP 1 - Trans: Module is performing transition: wakeup, or sleep, or sleep abortion 2 - Idle: Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 - Disable: Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	2h	Control the way mandatory clocks are managed. 0 - DISABLED: Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 - RESERVED_1: Reserved 2 - ENABLE: Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 - RESERVED: Reserved

7.2.5.0.10.50 CM_PER_L4HS_CLKSTCTRL Register (offset = 11Ch)

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_PER_L4HS_CLKSTCTRL is shown in Figure 7-98 and described in Table 7-110.

Figure 7-98. CM_PER_L4HS_CLKSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-110. CM_PER_L4HS_CLKSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	Reserved	R	0h	
6	CLKACTIVITY_CPSW_5MHZ_GCLK	R	1h	This field indicates the state of the CPSW_5MHZ_GCLK clock in the domain. 0 - Inact 1 - Act
5	CLKACTIVITY_CPSW_50MHZ_GCLK	R	1h	This field indicates the state of the CPSW_50MHZ_GCLK clock in the domain. 0 - Inact 1 - Act
4	CLKACTIVITY_CPSW_250MHZ_GCLK	R	1h	This field indicates the state of the CPSW_250MHZ_GCLK clock in the domain. 0 - Inact 1 - Act
3	CLKACTIVITY_L4HS_GCLK	R	1h	This field indicates the state of the L4HS_GCLK clock in the domain. 0 - Inact 1 - Act
2	Reserved	R	0h	
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the L4 Fast clock domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.10.54 CM_PER_OCPWP_L3_CLKSTCTRL Register (offset = 12Ch)

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_PER_OCPWP_L3_CLKSTCTRL is shown in Figure 7-102 and described in Table 7-114.

Figure 7-102. CM_PER_OCPWP_L3_CLKSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-114. CM_PER_OCPWP_L3_CLKSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	Reserved	R	0h	
5	CLKACTIVITY_OCPWP_L4_GCLK	R	0h	This field indicates the state of the OCPWP L4 clock in the domain. 0 - Inact 1 - Act
4	CLKACTIVITY_OCPWP_L3_GCLK	R	0h	This field indicates the state of the OCPWP L3 clock in the domain. 0 - Inact 1 - Act
3-2	Reserved	R	0h	
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the OCPWP clock domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.12.1 CM_WKUP_CLKSTCTRL Register (offset = 0h)

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

CM_WKUP_CLKSTCTRL is shown in Figure 7-132 and described in Table 7-146.

Figure 7-132. CM_WKUP_CLKSTCTRL Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 7-146. CM_WKUP_CLKSTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	Reserved	R	0h	
14	CLKACTIVITY_ADC_FCLK	R	0h	This field indicates the state of the ADC clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
13	CLKACTIVITY_TIMER1_GCLK	R	0h	This field indicates the state of the TIMER1 clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
12	CLKACTIVITY_UART0_GFCLK	R	0h	This field indicates the state of the UART0 clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
11	CLKACTIVITY_I2C0_GFCLK	R	0h	This field indicates the state of the I2C0 clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
10	CLKACTIVITY_TIMER0_GCLK	R	0h	This field indicates the state of the WKUPTIMER_GCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
9	CLKACTIVITY_WDT0_GCLK	R	0h	This field indicates the state of the WDT0_GCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
8	CLKACTIVITY_GPIO0_GDBCLK	R	0h	This field indicates the state of the WKUPGPIO_DBGICLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
7-5	Reserved	R	0h	
4	CLKACTIVITY_WDT1_GCLK	R	0h	This field indicates the state of the WDT1_GCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
3	CLKACTIVITY_SR_SYSCLK	R	0h	This field indicates the state of the SMARTREFGLEX SYSCLK clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
2	CLKACTIVITY_L4_WKUP_GCLK	R	1h	This field indicates the state of the L4_WKUP clock in the domain. 0 - Inact: Corresponding clock is gated 1 - Act: Corresponding clock is active
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the always on clock domain. 0 - NO_SLEEP: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 - SW_SLEEP: SW_SLEEP: Start a software forced sleep transition on the domain. 2 - SW_WKUP: SW_WKUP: Start a software forced wake-up transition on the domain. 3 - HW_AUTO: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

7.2.5.0.12.3 CM_CLKSEL_DPLL_CORE Register (offset = 68h)

This register provides controls over the DPLL.

CM_CLKSEL_DPLL_CORE is shown in Figure 7-134 and described in Table 7-148.

Figure 7-134. CM_CLKSEL_DPLL_CORE Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-148. CM_CLKSEL_DPLL_CORE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	Reserved	R	0h	
22-19	Reserved	R	0h	
18-8	DPLL_MULT	R/W	0h	DPLL multiplier factor (2 to 2047). This register is automatically cleared to 0 when the DPLL_EN field in the *CLKMODE_DPLL* register is set to select MN Bypass mode. (equal to input M of DPLL; M=2 to 2047 => DPLL multiplies by M) 0 - Reserved_0: Reserved 1 - Reserved_1: Reserved
7	Reserved	R	0h	
6-0	DPLL_DIV	R/W	0h	DPLL divider factor (0 to 127) (equal to input N of DPLL; actual division factor is N+1).

7.2.5.0.12.12 CM_CLKMODE_DPLL_MPU Register (offset = 88h)

This register allows controlling the DPLL modes.

CM_CLKMODE_DPLL_MPU is shown in Figure 7-143 and described in Table 7-157.

Figure 7-143. CM_CLKMODE_DPLL_MPU Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-157. CM_CLKMODE_DPLL_MPU Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	Reserved	R	0h	
15	DPLL_SSC_TYPE	R/W	0h	Select between Triangular and SquareWave Spread Spectrum Clocking 0 - Triangular: Triangular Spread Spectrum Clocking is selected 1 - Square: Square Wave Spread Spectrum Clocking is selected (only available under proper licensing agreement)
14	DPLL_SSC_DOWNSPREAD	R/W	0h	Control if only low frequency spread is required 0 - FULL_SPREAD: When SSC is enabled, clock frequency is spread on both sides of the programmed frequency 1 - LOW_SPREAD: When SSC is enabled, clock frequency is spread only on the lower side of the programmed frequency
13	DPLL_SSC_ACK	R	0h	Acknowledgement from the DPLL regarding start and stop of Spread Spectrum Clocking feature 0 - Disabled: SSC has been turned off on PLL o/ps 1 - Enabled: SSC has been turned on on PLL o/ps
12	DPLL_SSC_EN	R/W	0h	Enable or disable Spread Spectrum Clocking 0 - Disabled: SSC disabled 1 - Enabled: SSC enabled
11	DPLL_REGM4XEN	R	0h	Enable the REGM4XEN mode of the DPLL. Please check the DPLL documentation to check when this mode can be enabled. 0 - DISABLED: REGM4XEN mode of the DPLL is disabled
10	DPLL_LPMODE_EN	R/W	0h	Set the DPLL in Low Power mode. Check the DPLL documentation to see when this can be enabled. 0 - DISABLED: Low power mode of the DPLL is disabled 1 - ENABLED: Low power mode of the DPLL is enabled
9	DPLL_RELOCK_RAMP_EN	R/W	0h	If enabled, the clock ramping feature is used applied during the lock process, as well as the relock process. If disabled, the clock ramping feature is used only during the first lock.
8	DPLL_DRIFTGUARD_EN	R/W	0h	This bit allows to enable or disable the automatic recalibration feature of the DPLL. The DPLL will automatically start a recalibration process upon assertion of the DPLL's RECAL flag if this bit is set. 0 - Diasbled: DRIFTGUARD feature is disabled 1 - Enabled: DRIFTGUARD feature is enabled
7-5	DPLL_RAMP_RATE	R/W	0h	Selects the time in terms of DPLL REFCLKs spent at each stage of the clock ramping process 0 - REFCLKx2: 2 REFCLKs 1 - REFCLKx4: 4 REFCLKs 2 - REFCLKx8: 8 REFCLKs 3 - REFCLKx16: 16 REFCLKs 4 - REFCLKx32: 32 REFCLKs 5 - REFCLKx64: 64 REFCLKs 6 - REFCLKx128: 128 REFCLKs 7 - REFCLKx512: 512 REFCLKs

7.2.5.0.12.17 CM_CLKSEL_DPLL_PERIPH Register (offset = 9Ch)

This register provides controls over the DPLL.

CM_CLKSEL_DPLL_PERIPH is shown in Figure 7-148 and described in Table 7-162.

Figure 7-148. CM_CLKSEL_DPLL_PERIPH Register

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-162. CM_CLKSEL_DPLL_PERIPH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	DPLL_SD_DIV	R/W	0h	Sigma-Delta divider select (2-255). This factor must be set by s/w to ensure optimum jitter performance. DPLL_SD_DIV = CEILING ([DPLL_MULT/(DPLL_DIV+1)] * CLKINP / 250), where CLKINP is the input clock of the DPLL in MHz). Must be set with M and N factors, and must not be changed once DPLL is locked. 0 - Reserved: Reserved 1 - Reserved1: Reserved
23	Reserved	R	0h	
22-20	Reserved	R	0h	
19-8	DPLL_MULT	R/W	0h	DPLL multiplier factor (2 to 4095). This register is automatically cleared to 0 when the DPLL_EN field in the *CLKMODE_DPLL* register is set to select MN Bypass mode. (equal to input M of DPLL; M=2 to 4095 => DPLL multiplies by M). 0 - 0: Reserved 1 - 1: Reserved
7-0	DPLL_DIV	R/W	0h	DPLL divider factor (0 to 255) (equal to input N of DPLL; actual division factor is N+1).

9.5.1.1 L3 Initiator Agent (L3 IA) Register Mapping Summary

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- IVA2.2 subsystem port
- SGX subsystem port
- High-Speed USB Host
- High-Speed USB OTG
- System DMA read port
- System DMA write port
- Display subsystem port
- Camera subsystem port
- DAP port
- Die-to-die

Table 9-2 through Table 9-5 list the IA registers and their physical addresses, depending on the module instance.

Table 9-2. Initiator Agent Common Register Mapping Summary

9.5.1.3 L3 Target Agent (L3 TA) Register Mapping Summary

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- Master D2D (TA_MAD2D module)
- IVA2.2 subsystem (TA_IVA2.2 module)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

Table 9-10 through Table 9-13 lists all initiator target registers and their physical addresses depending on the module instance.

Figure 9-5 through Figure 9-8 describe the individual common registers in the module instance.

Table 9-10. Target Agent Common Register Mapping Summary

9.5.1.7 Protection Mechanism (PM) Register Mapping Summary

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IVA2.2 subsystem (PM_IVA2.2 module)

Table 9-22 and Table 9-24 list the protection registers and their physical addresses, depending on the module instance.

Figure 9-12 through Table 9-30 describe the individual common registers in the module instance.

Table 9-22. Protection Mechanism Common Register Mapping Summary

9.5.2.1 L4 Initiator Agent (L4 IA) Register Mapping Summary

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in Table 9-44 to Table 9-45.

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 9-44. L4 IA Register Mapping Summary (1)

9.5.2.2 L4 Initiator Agent (L4 IA) Register Descriptions

9.5.2.2.1 L4_IA_AGENT_CONTROL_L

This register enables error reporting on an initiator interface. The error reporting mechanism is enabled when the INBAND_ERROR_REP bit field is set to 1. The out-of-band OCP MError reporting mechanism is enabled when the MERROR_REP bit field is set to 1.

The L4_IA_AGENT_CONTROL_L is shown in Figure 9-23 and described in Table 9-46.

Figure 9-23. L4_IA_AGENT_CONTROL_L

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-46. L4_IA_AGENT_CONTROL_L Field Descriptions

Bit	Field	Value	Description
3128	Reserved	0	Read returns 0
27	INBAND_ ERROR_REP		Setting this field to 1 reports on in-band errors using the INBAND_ERROR log bit of IA.AGENT_STATUS register.
26-25	Reserved	0	Read returns 0
24	MERROR_REP		Enable MError reporting
23-0	Reserved	0	Read returns 0

9.5.2.2.2 L4_IA_AGENT_STATUS_L

This register stores status information for an initiator. The INBAND_ERROR and MERROR fields are read/write and are implemented as log bits.

The L4_IA_AGENT_STATUS_L is shown in Figure 9-24 and described in Table 9-47.

Figure 9-24. L4_IA_AGENT_STATUS_L

Table 9-47. L4_IA_AGENT_STATUS_L Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved
27	INBAND_ ERROR_REP	0x0 0x1	No In-Band error present In-Band error present
26-25	Reserved	0	Reserved
24	MERROR_REP	0x0 0x1	No MError error present MErorr error present
23-0	Reserved	0	Reserved

9.5.2.2.3 L4_IA_ERROR_LOG_L

This register logs information about error conditions. The CODE field logs any protection violation or address hole errors detected by the initiator subsystem while decoding a request.

The L4_IA_ERROR_LOG_L is shown in Figure 9-25 and described in Table 9-48.

Figure 9-25. L4_IA_ERROR_LOG_L

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-48. L4_IA_ERROR_LOG_L Field Descriptions

Bit	Field	Value	Description
31	MULTI		While the CODE field is not zero, the MULTI bit is asserted whenever an additional error is detected. Once set by hardware, the MULTI bit can only be cleared by writing a 1 to it while writing a value other than zero to the CODE field.
30-26	Reserved	0	Read returns 0.

Table 9-48. L4_IA_ERROR_LOG_L Field Descriptions (continued)

Bit	Field	Value	Description
25-24	CODE		The error code of an initiator request.
		0x00	No errors
		0x01	Reserved
		0x10	Address hole
		0x11	Protection violation
			The CODE field, once set by hardware, can only be cleared by writing a non-zero value to it, in conjunction with writing a 1 to the MULTI bit field.
23-0	Reserved	0	Read returns 0.

9.5.2.3 L4 Target Agent (L4 TA) Register Mapping Summary

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in Table 9-49 to Table 9-77.

Table 9-49 to Table 9-78 provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

9.5.2.4 L4 Target Agent (L4 TA) Register Descriptions

9.5.2.4.1 L4_TA_AGENT_CONTROL_L

This register enables error reporting. The L4_TA_AGENT_CONTROL_L is shown in Figure 9-26 and described in Table 9-79.

Figure 9-26. L4_TA_AGENT_CONTROL_L

31 – 25	24
Reserved	SERROR_REP
	R

23 – 11	10 – 8	7 – 1	0
Reserved	REQ_TIMEOUT	Reserved	OCP_RESET
	RW		R/W

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-79. L4_TA_AGENT_CONTROL_L Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Read returns 0.
24	SERROR_REP		Enable logging of error
23-11	Reserved	0	Read returns 0.
10-8	REQ_TIMEOUT		Timeout Bound. Values are:0 - No timeout
		1	1x base cycles
		2	4x base cycles
		3	16x base cycles
		4	64x base cycles
7-1	Reserved		Read returns 0.
0	OCP_RESET		The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to de-assert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.

9.5.2.5 L4 Link Register Agent (LA) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in Table 9-82.

The LA register block contains the initiator subsystem information register and the composite sideband signal mask and status registers.

Table 9-82. L4 LA Register Mapping Summary

Register Name	Type	Register Width (Bits)	CORE_LA Physical Address	PER_LA Physical Address	EMU_LA Physical Address	WKUP_LA Physical Address

Table 9-84. L4_LA_INITIATOR_INFO_L Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Read returns 0.
27-24	PROT_GROUPS		The number of protection groups. The PROT_GROUPS field contains read-only configuration information for the address mapping and security structure of the initiator subsystem. If the PROT_GROUPS field is set to 0, there are no protection group registers.
23-16	NUMBER_REGIONS		The number of regions. The NUMBER_REGIONS field contains read-only configuration information for the region register of the initiator subsystem.
15-4	Reserved	0	Read returns 0.
3-0	SEGMENTS		The number of segments. The SEGMENT fields contains read-only configuration information for the segment register of the initiator subsystem.

Table 9-85. Reset value for L4_LA_INITIATOR_INFO_L

Table 9-86. L4_LA_INITIATOR_INFO_H Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Read returns 0.
18-16	THREADS		The THREADS field specifies the number of initiator threads connected to the interconnect. The field contains read-only configuration information for the initiator subsystem.
15	Reserved	0	Read returns 0.
14-12	CONNID_WIDTH		The initiator subsystem connID width. The CONNID_WIDTH field contains read-only configuration information for the initiator subsystem.
11	Reserved	0	Read returns 0.
10-8	BYTE_DATA_WIDTH_EXP		This field specifies the initiator subsystem data width. 1:2^1 bytes specifies a 16-bit data width and 2:2^2 bytes specifies a 32-bit data width. The BYTE_DATA_WIDTH_EXP field contains read-only configuration information for the initiator subsystem.
7-5	Reserved	0	Read returns 0.
4-0	ADDR_WIDTH		This field specifies the initiator subsystem address width. The ADDR_WIDTH field contains read-only configuration information for the initiator subsystem.

Table 9-88. L4_LA_NETWORK_CONTROL_L Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	Read returns 0.
10-8	TIMEOUT_BASE		The TIMEOUT_BASE field indicates the timeout period (that is, base cycles) for the highest frequency time-base signal sent from the L4 initiator subsystem to all target agents that have timeout enabled. Values for the field are:
		0	Timeout disabled
		1	L4 interconnect clock cycles divided by 64
		2	L4 interconnect clock cycles divided by 256
		3	L4 interconnect clock cycles divided by 1024
		4	L4 interconnect clock cycles divided by 4096
7-0	Reserved	0	Read returns 0.

9.5.2.6.5 L4_LA_NETWORK_CONTROL_H

This register controls interconnect global power control. The L4_LA_NETWORK_CONTROL_H is shown in Figure 9-33 and described in Table 9-89.

Figure 9-33. L4_LA_NETWORK_CONTROL_H

31–25	24	23–21	20	19–16
Reserved	CLOCK_GATE_DISABLE	Reserved	THREAD0_PRI	Reserved
	R/W		R	

15–9	8	7–0
Reserved	EXT_CLOCK	Reserved
	R	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-89. L4_LA_NETWORK_CONTROL_H Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Read returns 0.
24	CLOCK_GATE_DISABLE		When set to 1 this field disables all clock gating.
23-21	Reserved	0	Read returns 0.
20	THREAD0_PRI		Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.
19-9	Reserved	0	Read returns 0.
8	EXT_CLOCK		When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.
7-0	Reserved	0	Read returns 0.

9.5.2.7 L4 Address Protection (AP) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in Table 9-90.

The AP register block contains the segment, address region, and protection group registers that can be used to specify the addressing scheme or restrict the access of target address regions.

Table 9-90. L4 AP Register Mapping Summary

Register Name	Type	Register Width (Bits)	CORE_AP Physical Address	PER_AP Physical Address	Section

9.5.2.8 L4 Address Protection (AP) Register Descriptions

9.5.2.8.1 L4_AP_SEGMENT_i_L

This register defines the base address of each segments. The L4_AP_SEGMENT_i_L is shown in Figure 9-34 and described in Table 9-96.

Figure 9-34. L4_AP_SEGMENT_i_L

Table 9-98. L4_AP_SEGMENT_i_H Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Read returns 0.
4-0	SIZE		Segment size is a power of 2, where 2^SIZE is the byte size of a segment (all segment registers use the same size).

Table 9-99. Reset Values for L4_AP_SEGMENT_i_H

SIZE	CORE_AP	PER_AP	EMU_AP	WKUP_AP
For all i	0x12	0x10	0x15	0x11

9.5.2.8.3 L4_AP_PROT_GROUP_MEMBERS_k_L

This register defines connID bit vectors for a protection group. The L4_AP_PROT_GROUP_MEMBERS_k_L is shown in Figure 9-36 and described in Table 9-100.

Figure 9-36. L4_AP_PROT_GROUP_MEMBERS_k_L

9.5.2.8.4 L4_AP_PROT_GROUP_ROLES_k_L

This register defines MReqInfo bit vectors for a protection group. The L4_AP_PROT_GROUP_ROLES_k_L is shown in Figure 9-37 and described in Table 9-101.

Figure 9-37. L4_AP_PROT_GROUP_ROLES_k_L

Bit	Field	Value	Description
31-16	Reserved	0	Read returns 0.
15-0	ENABLE		Setting of type access allowed for the group of initiators.

9.5.2.8.5 L4_AP_REGION_l_L

This register defines the base address of the region in respect to the segment it belongs to. The L4_AP_REGION_l_L is shown in Figure 9-38 and described in Table 9-102.

Figure 9-38. L4_AP_REGION_l_L

9.5.2.8.6 L4_AP_REGION_l_H

This register defines the size, protection group^and segment ID of the region. The L4_AP_REGION_l_H is shown in Figure 9-39 and described in Table 9-103.

Figure 9-39. L4_AP_REGION_l_H

31–28	27–24	23	22–20	19–17	16

15–6	5–1	0
Reserved	SIZE	ENABLE
	R	R

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-103. L4_AP_REGION_l_H Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Read returns 0
27-24	SEGMENT_ID		Identifies the segment to which the region is part of.
23	Reserved	0	Read returns 0
22-20	PROT_GROUP_ID		The protection group containing this region.
19-17	BYTE_DATA_WIDTH_EXP		The target OCP data byte width is 2^(BYTE_DATA_WIDTH_EXP) bytes. The value of this field is derived from the target OCP data_width parameter.
16-6	Reserved	0	Read returns 0
5-1	SIZE		Define the size of the region in bytes. 2^SIZE equals the region.
0	ENABLE	0x0 0x1	Disable the region, no access allows Enable the region, with access as define in registers

10.5 EDMA3 Registers

This section discusses the registers of the EDMA3 controller.

10.5.1 Register Memory Maps

See your device-specific data manual for the register memory maps.

10.5.2 EDMA3 Channel Controller Control Registers

Table 10-1 lists the memory-mapped registers for the EDMA3 channel controller (EDMACC). See the device-specific data manual for the memory address of these registers, and for the shadow region addresses. All other register offset addresses not listed in Table 10-1 should be considered as reserved locations and the register contents should not be modified.

Table 10-1. EDMACC Registers

Offset	Acronym	Register Description	Section
00h	PID	Peripheral Identification Register	Section 10.5.2.1.1

10.5.2.1.2 EDMA3CC Configuration Register (CCCFG)

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device.

The CCCFG is shown in Figure 10-2 and described in Table 10-3.

10.5.2.1.4 QDMA Channel Map *n* Registers (QCHMAP*n*)

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map *n* register (QCHMAP*n*).

The QCHMAP*n* is shown in Figure 10-4 and described in Table 10-5.

NOTE: At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP*n* is programmed appropriately to point to a different PaRAM entry.

10.5.2.1.5 DMA Channel Queue *n* Number Registers (DMAQNUM*n*)

The DMA channel queue number register (DMAQNUM*n*) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0.

The DMAQNUM*n* is shown in Figure 10-5 and described in Table 10-6. Table 10-7 shows the channels and their corresponding bits in DMAQNUM*n*.

NOTE: Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM*n* for a particular DMA channel *n* also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

Figure 10-5. DMA Channel Queue *n* Number Registers (DMAQNUM*n*)

10.5.2.1.6 QDMA Channel Queue Number Register (QDMAQNUM)

The QDMA channel queue number register (QDMAQNUM) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC.

The QDMAQNUM is shown in Figure 10-6 and described in Table 10-8.

10.5.2.1.7 Queue Priority Register (QUEPRI)

The queue priority register (QUEPRI) allows you to change the priority of the individual queues and the priority of the transfer request (TR) associated with the events queued in the queue. Because the queue to EDMA3TC mapping is fixed, programming QUEPRI essentially governs the priority of the associated transfer controller(s) read/write commands with respect to the other bus masters in the device. You can modify the EDMA3TC priority to obtain the desired system performance.

The QUEPRI is shown in Figure 10-7 and described in Table 10-9.

Figure 10-7. Queue Priority Register (QUEPRI)

31–16	15	14–12	11	10–8	7	6–4	3	2–0

10.5.2.2 Error Registers

The EDMA3CC contains a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

10.5.2.2.1 Event Missed Registers (EMR/EMRH)

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The EMR is shown in Figure 10-8 and described in Table 10-10. The EMRH is shown in Figure 10-9 and described in Table 10-11.

10.5.2.2.2 Event Missed Clear Registers (EMCR/EMCRH)

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect.

The EMCR is shown in Figure 10-10 and described in Table 10-12. The EMCRH is shown in Figure 10-11 and described in Table 10-13.

Figure 10-10. Event Missed Clear Register (EMCR)

10.5.2.2.3 QDMA Event Missed Register (QEMR)

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*.

The QEMR is shown in Figure 10-12 and described in Table 10-14.

10.5.2.2.4 QDMA Event Missed Clear Register (QEMCR)

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect.

The QEMCR is shown in Figure 10-13 and described in Table 10-15.

Figure 10-13. QDMA Event Missed Clear Register (QEMCR)

7-0	E*n*		QDMA event missed clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC.
		0	No effect.
		1	Corresponding missed event bit in the QDMA event missed register (QEMR) is cleared (E*n* = 0).

10.5.2.2.5 EDMA3CC Error Register (CCERR)

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see *Error Interrupts*. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR).

The CCERR is shown in Figure 10-14 and described in Table 10-16.

Figure 10-14. EDMA3CC Error Register (CCERR)

Table 10-16. EDMA3CC Error Register (CCERR) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
16	TCCERR		Transfer completion code error. TCCERR is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Total number of allowed TCCs outstanding has not been reached.
		1	Total number of allowed TCCs has been reached.
15-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	QTHRXCD3		Queue threshold error for queue 3. QTHRXCD3 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
2	QTHRXCD2		Queue threshold error for queue 2. QTHRXCD2 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
1	QTHRXCD1		Queue threshold error for queue 1 . QTHRXCD1 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.
0	QTHRXCD0		Queue threshold error for queue 0. QTHRXCD0 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR).
		0	Watermark/threshold has not been exceeded.
		1	Watermark/threshold has been exceeded.

10.5.2.2.6 EDMA3CC Error Clear Register (CCERRCLR)

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTAT*n*) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect.

The CCERRCLR is shown in Figure 10-15 and described in Table 10-17.

10.5.2.2.7 Error Evaluation Register (EEVAL)

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an “all the error bits cleared” to “at least one error bit is set”. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect.

The EEVAL is shown in Figure 10-16 and described in Table 10-18.

Figure 10-16. Error Evaluation Register (EEVAL)

10.5.2.3 Region Access Enable Registers

The region access enable register group consists of the DMA access enable registers (DRAE*m* and DRAEH*m*) and the QDMA access enable registers (QRAE*m*). Where *m* is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

10.5.2.3.1 DMA Region Access Enable for Region m (DRAEm)

The DMA region access enable register for shadow region *m* (DRAE*m*/DRAEH*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region *m* view of the DMA channel registers. See the EDMA3CC register memory map (Table 10-1) for a list of all the DMA channel and interrupt registers mapped in the shadow region view. Additionally, the DRAE*m*/DRAEH*m* configuration determines completion of which DMA channels will result in assertion of the shadow region *m* DMA completion interrupt (see *EDMA3 Interrupts*).

The DRAE*m* is shown in Figure 10-17 and described in Table 10-19. The DRAEH*m* is shown in Figure 10-18 and described in Table 10-19.

Bit	Field	Value	Description
31-0	E*n*		DMA region access enable for bit *n*/channel *n* in region *m*.
		0	Accesses via region *m* address space to bit *n* in any DMA channel register are not allowed. Reads return 0 on bit *n* and writes do not modify the state of bit *n*. Enabled interrupt bits for bit *n* do not contribute to the generation of a transfer completion interrupt for shadow region *m*.
		1	Accesses via region *m* address space to bit *n* in any DMA channel register are allowed. Reads return the value from bit *n* and writes modify the state of bit *n*. Enabled interrupt bits for bit *n* contribute to the generation of a transfer completion interrupt for shadow region *m*.

10.5.2.3.2 QDMA Region Access Enable Registers (QRAEm)

The QDMA region access enable register for shadow region *m* (QRAE*m*) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region *m* view of the QDMA registers. This includes all 4-bit QDMA registers.

The QRAE*m* is shown in Figure 10-19 and described in Table 10-20.

10.5.2.4 Status/Debug Visibility Registers

The following set of registers provide visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

10.5.2.4.1 Event Queue Entry Registers (QxEy)

The event queue entry registers (Q*x*E*y*) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC.

There are Q0E0 to Q0E15, Q1E0 to Q1E15, Q2E0 to Q2E15, and Q3E0 to Q3E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15.

The Q*x*E*y* is shown in Figure 10-20 and described in Table 10-21.

Figure 10-20. Event Queue Entry Registers (Q*x*E*y*)

31–16	15–8	7–6	5–0
Reserved	Reserved	ETYPE	ENUM
R-0	R-0	R-x	R-x

LEGEND: R = Read only; -*n* = value after reset; -x = value is indeterminate after reset

Table 10-21. Event Queue Entry Registers (Q*x*E*y*) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-6	ETYPE	0-3h	Event entry *y* in queue *x*. Specifies the specific event type for the given entry in the event queue.
		0	Event triggered via ER.
		1h	Manual triggered via ESR.
		2h	Chain triggered via CER.
		3h	Auto-triggered via QER.
5-0	ENUM	0-3Fh	Event entry *y* in queue *x*. Event number:
		0-3h	QDMA channel number (0 to 3).
		0-3Fh	DMA channel/event number (0 to 63).

LEGEND: R = Read only; -*n* = value after reset

Table 10-22. Queue Status Register *n* (QSTAT*n*) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
24	THRXCD		Threshold exceeded. THRXCD is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR).
		0	Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has not been exceeded.
		1	Threshold specified by the Q*n* bit in the queue watermark threshold A register (QWMTHRA) has been exceeded.
23-21	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
20-16	WM	0-10h	Watermark for maximum queue usage. Watermark tracks the most entries that have been in queue *n* since reset or since the last time that the watermark (WM) bit was cleared. WM is cleared by writing a 1 to the corresponding QTHRXCD*n* bit in the EDMA3CC error clear register (CCERRCLR).
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
12-8	NUMVAL	0-10h	Number of valid entries in queue *n*. The total number of entries residing in the queue manager FIFO at a given instant. Always enabled.
		0-10h	Legal values are 0 (empty) to 10h (full).
		11h-1Fh	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STRTPTR	0-Fh	Start pointer. The offset to the head entry of queue *n*, in units of entries. Always enabled. Legal values are 0 (0th entry) to Fh (15th entry).

31-20	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
19	QUEACTV3		Queue 3 active.
		0	No events are queued in queue 3.
		1	At least one TR is queued in queue 3.
18	QUEACTV2		Queue 2 active.
		0	No events are queued in queue 2.
		1	At least one TR is queued in queue 2.
17	QUEACTV1		Queue 1 active.
		0	No events are queued in queue 1.
		1	At least one TR is queued in queue 1.
16	QUEACTV0		Queue 0 active.
		0	No events are queued in queue 0.
		1	At least one TR is queued in queue 0.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-8	COMPACTV	0-3Fh	Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less then 63 (or return a transfer completion code from a transfer controller, which would decrement the count).
		0	No completion requests outstanding.
		1h-3Fh	Total of 1 completion request to 63 completion requests are outstanding.
7-5	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

10.5.2.6 DMA Channel Registers

The following sets of registers pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUM*n*) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format *reg_name* that corresponds to DMA channels 0 through 31 and *reg_name_High* that corresponds to DMA channels 32 through 64.

For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register.

The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAE*m*/DRAEH*m*). The registers are described in Section 10.5.2.3.1 and the details for shadow region/global region usage is explained in *EDMA3 Channel Controller Regions*.

10.5.2.6.1 Event Registers (ER, ERH)

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.E*n*/EERH.E*n* = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.E*n*/ERH.E*n* = 0) once the corresponding events are prioritized and serviced. If ER.E*n*/ERH.E*n* are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.E*n*/EMRH.E*n*), provided that the event was enabled (EER.E*n*/EERH.E*n* = 1).

Event *n* can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The *Debug List* table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events.

10.5.2.6.2 Event Clear Registers (ECR, ECRH)

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH).

Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH.

The ECR is shown in Figure 10-30 and described in Table 10-31. The ECRH is shown in Figure 10-31 and described in Table 10-32.

10.5.2.6.3 Event Set Registers (ESR, ESRH)

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (E*n*) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect.

The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.E*n*/EERH.E*n*).

Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.E*n*/ESRH.E*n* bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1).

The ESR is shown in Figure 10-32 and described in Table 10-33. The ESRH is shown in Figure 10-33 and described in Table 10-34.

10.5.2.6.4 Chained Event Registers (CER, CERH)

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer.

The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The E*n* bit is set (regardless of the state of EER.E*n*/EERH.E*n*) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced.

If the E*n* bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.E*n*/EMRH.E*n* = 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The CER is shown in Figure 10-34 and described in Table 10-35. The CERH is shown in Figure 10-35 and described in Table 10-36.

10.5.2.6.5 Event Enable Registers (EER, EERH)

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event.

The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.E*n*/CERH.E*n* = 1) and manually set events (ESR.E*n*/ESRH.E*n* = 1).

The EER is shown in Figure 10-36 and described in Table 10-37. Th EERH is shown in Figure 10-37 and described in Table 10-38.

10.5.2.6.6 Event Enable Clear Register (EECR, EECRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EECR is shown in Figure 10-38 and described in Table 10-39. The EECRH is shown in Figure 10-39 and described in Table 10-40.

Figure 10-38. Event Enable Clear Register (EECR)

10.5.2.6.7 Event Enable Set Registers (EESR, EESRH)

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable set registers (EESR/EESRH) are used to enable events. Writes of 1 to the bits in EESR/EESRH set the corresponding event bits in EER/EERH; writes of 0 have no effect.

The EESR is shown in Figure 10-40 and described in Table 10-41. The EESRH is shown in Figure 10-41 and described in Table 10-42.

10.5.2.6.8 Secondary Event Registers (SER, SERH)

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.E*n*/ESRH.E*n* = 1, ER.E*n*/ERH.E*n* = 1, or CER.E*n*/CERH.E*n* = 1), which results in the setting of a corresponding event bit in SER/SERH (SER.E*n*/SERH.E*n* = 1), it implies that the corresponding DMA event is in the queue.

Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see *EDMA Overview*.

The SER is shown in Figure 10-42 and described in Table 10-43. The SERH is shown in Figure 10-43 and described in Table 10-44.

Figure 10-42. Secondary Event Register (SER)

10.5.2.7 Interrupt Registers

All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. The following set of registers is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see *EDMA3 Interrupts*.

10.5.2.7.1 Interrupt Enable Registers (IER, IERH)

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH).

The IER is shown in Figure 10-46 and described in Table 10-47. The IERH is shown in Figure 10-47 and described in Table 10-48.

10.5.2.7.2 Interrupt Enable Clear Register (IECR, IECRH)

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

10.5.2.7.3 Interrupt Enable Set Registers (IESR, IESRH)

The interrupt enable set registers (IESR/IESRH) are used to enable interrupts. Writes of 1 to the bits in IESR/IESRH set the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect.

The IESR is shown in Figure 10-50 and described in Table 10-51. The IESRH is shown in Figure 10-51 and described in Table 10-52.

10.5.2.7.4 Interrupt Pending Register (IPR, IPRH)

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel.

When an interrupt transfer completion code with TCC = *n* is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.I*n*, if *n* = 0 to 31; IPRH.I*n*, if *n* = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH).

The IPR is shown in Figure 10-52 and described in Table 10-53. The IPRH is shown in Figure 10-53 and described in Table 10-54.

10.5.2.7.5 Interrupt Clear Registers (ICR, ICRH)

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts.

10.5.2.7.6 Interrupt Evaluate Register (IEVAL)

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAE*m*/DRAEH*m*, QRAE*n*/QRAEH*n*). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU.

The IEVAL is shown in Figure 10-56 and described in Table 10-57.

Figure 10-56. Interrupt Evaluate Register (IEVAL)

31				16
Reserved				
R-0				

15	2	1	0

R-0		W-0	W-0

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 10-57. Interrupt Evaluate Register (IEVAL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	EVAL		Interrupt evaluate.
		0	No effect.
		1	Causes EDMA3CC completion interrupt to be pulsed, if any enabled (IER*n*/IERH*n* = 1) interrupts are still pending (IPR*n*/IPRH*n* = 1).
			The EDMA3CC completion interrupt that is pulsed depends on which IEVAL is being exercised. For example, writing to the EVAL bit in IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt.

10.5.2.8 QDMA Registers

The following sets of registers control the QDMA channels in the EDMA3CC. The QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAE*n*/QRAEH*n*). *EDMA3 Channel Controller Regions* details shadow region/global region usage.

10.5.2.8.1 QDMA Event Register (QER)

The QDMA event register (QER) channel *n* bit is set (E*n* = 1) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAP*n*)) in the PaRAM entry associated with QDMA channel *n* (which is also programmed using QCHMAP*n*). The E*n* bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAP*n* settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel *n* bit is also enabled (QEER.E*n* = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. For additional conditions that can lead to the setting of QER bits, see *EDMA Overview*.

The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues.

The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the E*n* bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR (E*n* = 1).

The QER is shown in Figure 10-57 and described in Table 10-58.

10.5.2.8.2 QDMA Event Enable Register (QEER)

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER.

The QEER is shown in Figure 10-58 and described in Table 10-59.

Figure 10-58. QDMA Event Enable Register (QEER)

10.5.2.8.3 QDMA Event Enable Clear Register (QEECR)

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

The QEECR is shown in Figure 10-59 and described in Table 10-60.

10.5.2.8.5 QDMA Secondary Event Register (QSER)

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. For additional conditions that can cause the secondary event registers (QSER\SER) to be set, see *EDMA Overview*.

The QSER is shown in Figure 10-61 and described in Table 10-62.

10.5.2.8.6 QDMA Secondary Event Clear Register (QSECR)

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers.

The QSECR is shown in Figure 10-62 and described in Table 10-63.

10.5.3.3 EDMA3TC Channel Status Register (TCSTAT)

The EDMA3TC channel status register (TCSTAT) is shown in Figure 10-65 and described in Table 10-67.

Figure 10-65. EDMA3TC Channel Status Register (TCSTAT)

31–16	15–14	13–12	11–9	8	7	6–4	3	2	1	0
Reserved	Reserved	DFSTRTPTR	Reserved	Reserved	Reserved	DSTACTV	Reserved	WSACTV	SRCACTV	PROGBUSY
R-0	R-0	R-0	R-0	R-1	R-0	R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 10-67. EDMA3TC Channel Status Register (TCSTAT) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13-12	DFSTRTPTR	0-3h	Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries.
11-9	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
8	Reserved	1	Reserved. Always read as 1.
7	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
6-4	DSTACTV	0-7h	Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter.
		0	Destination FIFO is empty.
		1h	Destination FIFO contains 1 TR.
		2h	Destination FIFO contains 2 TRs.
		3h	Destination FIFO contains 3 TRs.
		4h	Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4).
			If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle.
			If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed.
		5h-7h	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
2	WSACTV		Write status active
		0	Write status is not pending. Write status has been received for all previously issued write commands.
		1	Write status is pending. Write status has not been received for all previously issued write commands.
1	SRCACTV		Source active state
		0	Source controller is idle. Source active register set contains a previously processed transfer request.
		1	Source controller is busy servicing a transfer request.

R-0	R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 10-68. Error Register (ERRSTAT) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR		MMR address error.
		0	Condition is not detected.
		1	User attempted to read or write to an invalid address in configuration memory map.
2	TRERR		Transfer request (TR) error event.
		0	Condition is not detected.
		1	TR detected that violates constant addressing mode transfer (SAM or DAM is set) alignment rules or has ACNT or BCNT == 0.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR		Bus error event.
		0	Condition is not detected.
		1	EDMA3TC has detected an error at source or destination address. Error information can be read from the error details register (ERRDET).

10.5.3.4.2 Error Enable Register (ERREN)

The error enable register (ERREN) is shown in Figure 10-67 and described in Table 10-69.

When any of the enable bits are set, a bit set in the corresponding ERRSTAT causes an assertion of the EDMA3TC interrupt.

Figure 10-67. Error Enable Register (ERREN)

31–16	15–4	3	2	1	0
Reserved	Reserved	MMRAERR	TRERR	Reserved	BUSERR
R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-69. Error Enable Register (ERREN) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	MMRAERR		Interrupt enable for MMR address error (MMRAERR).
		0	MMRAERR is disabled.
		1	MMRAERR is enabled and contributes to the state of EDMA3TC error interrupt generation
2	TRERR		Interrupt enable for transfer request error (TRERR).
		0	TRERR is disabled.
		1	TRERR is enabled and contributes to the state of EDMA3TC error interrupt generation.
1	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
0	BUSERR		Interrupt enable for bus error (BUSERR).
		0	BUSERR is disabled.
		1	BUSERR is enabled and contributes to the state of EDMA3TC error interrupt generation.

R-0		R-0		R-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-71. Error Details Register (ERRDET) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
17	TCCHEN	0-1	Transfer completion chaining enable. Contains the TCCHEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
16	TCINTEN	0-1	Transfer completion interrupt enable. Contains the TCINTEN value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
15-14	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
13 - 8	TCC	0-3Fh	Transfer complete code. Contains the TCC value in the channel options parameter (OPT) programmed by the channel controller for the read or write transaction that resulted in an error.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3-0	STAT	0-Fh	Transaction status. Stores the nonzero status/error code that was detected on the read status or write status bus. If read status and write status are returned on the same cycle, then the EDMA3TC chooses nonzero version. If both are nonzero, then the write status is treated as higher priority.
		0	No error.
		1h-7h	Read error.
		8h-Fh	Write error.

10.5.3.5 Read Rate Register (RDRATE)

The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads.

RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles.

The RDRATE is shown in Figure 10-71 and described in Table 10-73.

NOTE: It is expected that the RDRATE value for a transfer controller is static, as it is decided based on the application requirement. It is not recommended to change this setting on the fly.

Figure 10-71. Read Rate Register (RDRATE)

31			16

10.5.3.6 EDMA3TC Channel Registers

The EDMA3TC channel registers are split into three parts: the programming registers, the source active registers, and the destination FIFO register. This section describes the registers and their functions. The program register set is programmed by the channel controller, and is for internal use. The other two sets are read-only and provided to facilitate advanced debug capabilities. The number of destination FIFO register sets depends on the destination FIFO depth.

TC0 has a FIFO depth of 2, so there are two sets of destination FIFO registers associated with TC0. TC1, TC2, and TC3 have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

10.5.3.6.1 Source Active Options Register (SAOPT)

The source active options register (SAOPT) is shown in Figure 10-72 and described in Table 10-74.

Figure 10-72. Source Active Options Register (SAOPT)

31–23	22	21	20	19–18	17–16

11.1 Introduction

The touchscreen controller and analog-to-digital converter subsystem (TSC_ADC_SS) is an 8-channel general-purpose analog-to-digital converter (ADC) with optional support for interleaving touchscreen (TS) conversions for a 4-wire, 5-wire, or 8-wire resistive panel. The TSC_ADC_SS can be configured for use in one of the following applications:

- 8 general-purpose ADC channels
- 4-wire TSC with 4 general-purpose ADC channels
- 5-wire TSC with 3 general-purpose ADC channels
- 8-wire TSC

11.1.1 TSC_ADC Features

The main features of the TSC_ADC_SS include:

- Support for 4-wire, 5-wire, and 8-wire resistive TS panels
- Support for interleaving TS capture and general-purpose ADC modes
- Programmable FSM sequencer that supports 16 steps:
  - Software register bit for start of conversion
  - Optional start of conversion HW synchronized to Pen touch or external HW event (but not both)
  - Single conversion (one-shot)
  - Continuous conversions
  - Sequence through all input channels based on a mask
  - Programmable OpenDelay before sampling each channel
  - Programmable sampling delay for each channel
  - Programmable averaging of input samples - 16/8/4/2/1
  - Differential or singled ended mode setting for each channel
  - Store data in either of two FIFO groups
  - Option to encode channel number with data
  - Support for servicing FIFOs via DMA or CPU
  - Programmable DMA Request event (for each FIFO)
  - Dynamically enable or disable channel inputs during operation
  - Stop bit to end conversion
- Support for the following interrupts and status, with masking:
  - Interrupt for HW pen (touch) event
  - Interrupt for HW Pen Up event
  - Interrupt after a sequence of conversions (all non-masked channels)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

11.1.2 Unsupported TSC_ADC_SS Features

This device supports all TSC_ADC_SS features.

11.2.2 TSC_ADC Clock and Reset Management

The TSC_ADC has two clock domains. The ADC uses the adc_clk. The bus interfaces, FIFOs, sequencer, and all other lofic use the ocp_clk.

Table 11-2. TSC_ADC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk OCP / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_pwkup_l4_wkup_gclk From PRCM
adc_clk ADC clock	24 MHz (typ)	CLK_M_OSC	pd_wkup_adc_fclk From PRCM

11.2.3 TSC_ADC Pin List

The TSC_ADC external interface signals are shown in Table 11-3.

Table 11-3. TSC_ADC Pin List

Pin	Type	Description

11.3 Functional Description

Before enabling the TSC_ADC_SS module, the user must first program the Step Configuration registers in order to configure a channel input to be sampled. There are 16 programmable Step Configuration registers which are used by the sequencer to control which switches to turn on or off (inputs to the AFE), which channel to sample, , and which mode to use (HW triggered or SW enabled, one-shot or continuous, averaging, where to save the FIFO data, etc).

11.3.1 HW Synchronized or SW Channels

The user can control the start behavior of each channel input by deciding if a channel should be sampled immediately (SW enabled) after it is enabled, or if the channel should wait for a HW event to occur first (a HW event must either be mapped to the touch screen PEN event or mapped to theHW event input signal, but not both) . Each channel input can be configured independently via the Step Configuration register.

11.3.2 Open Delay and Sample Delay

The user can program the delay between driving the inputs to the AFE and the time to send the start of conversion signal. This delay can be used to allow the voltages to stabilize on the touch screen panel before sampling. This delay is called “open delay” and can also be programmed to zero. The user also has control of the sampling time (width of the start of conversion signal) to the AFE which is called the “sample delay”. Each channel input is configured independently via the Step Delay register.

11.3.3 Averaging of Samples (1, 2, 4, 8, and 16)

Each channel input has the capability to average the sampled data. The valid averaging options are 1 (no average), 2, 4, 8, and 16. If averaging is turned on, then the channel is immediately sampled again (up to 16 times) and final averaged sample data is stored in the FIFO. Each channel input can be independently configured via the Step Configuration registers.

11.3.4 One-Shot (Single) or Continuous Mode

When the sequencer finishes cycling through all the enabled steps , the user can decide if the sequencer should stop (one-shot), or loop back and schedule a the step again (continuous).

If one-shot mode is selected, the sequencer will take care of disabling the step enable bit after the conversion. If continuous mode is selected, it is the software’s responsibility to turn off the step enable bit.

11.3.5 Interrupts

The following interrupts are supported via enable bits, and also are maskable:

- HW_PEN down interrupt is generated when the user touches the screen
- PEN_UP interrupt is generated after the sequencer detects pen is lifted
- END_OF_SEQUENCE interrupt is generated after the last active step
- Each FIFO has a underflow or overrun interrupt
- Each FIFO has a programmable threshold interrupt
- An OUT_OF_RANGE interrupt is generated if sampled data is greater than programmable value, or less than a programmable value

See the *Interrupts* chapter for more information.

11.3.6 DMA Requests

Each FIFO group can be serviced by either a DMA or by the CPU. To generate DMA requests, the user must first enable the TSC_ADC_SS_DMAENABLE_SET Register. Also, the user can program the desired number of words to generate a DMA request using the TSC_ADC_SS_DMAREQ register. When the FIFO level reaches or exceeds that value, a DMA request is generated.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

The DMA slave port allows for burst reads in order to effectively move the FIFO data. Internally, the OCP DMA address (MSB) is decoded for either FIFO 0 or FIFO 1. The lower bits of the DMA addresses are ignored since the FIFO pointers are incremented internally. Refer to **section 5** (DMA) for more information.

11.3.7 AFE Functional Block Diagram

The AFE features are listed below, and some are controlled by the TSC_ADC_SS:

- ADC sampled data is 12-bit wide
- Sampling rate can be as fast as every 15 ADC clock cycles
- Support for internal ADC clock divider logic
- Support for configuring the delay between samples also the sampling time

11.4 Operational Modes

The sequencer is completely controlled by software and behaves accordingly to how the **Step Registers** are programmed. A **step** is the general term for sampling a channel input. It is defined by the programmer who decides which input values to send to the AFE (via the StepConfig register), and also how (via StepConfig register) and when (via StepDelay register) to sample a channel input.

A **step** consists of these three registers:

- **StepEnable** – enables or disables the step
- **StepConfig** - controls the input values to the ADC (the reference voltages, the pull up/down transistor biasing, which input channel to sample, differential control, HW synchronized or SW enabled, averaging, and which FIFO group to save the data)
- **StepDelay** - controls the OpenDelay (the time between driving the AFE inputs until sending the SOC signal to the AFE), and also controls the SampleDelay (the time between the rising edge of the start signal and the falling edge of the start signal)

The sequencer supports a total of 16 programmable steps, a Touchscreen Charge step, and an Idle step. Each step consists of the three registers above (StepEnable, StepConfig, and StepDelay), except the Idle step does not have a StepEnable bit (it must always be on), and it also does not have a StepDelay register. Also, during the Idle and Touch Screen Charge steps, the sequencer does not actually sample a channel after applying the StepConfiguration values.

Assuming all the steps are were configured as general purpose mode (no touchscreen), then the steps would be configured as SW enabled. When the TSC_ADC_SS is first enabled, the sequencer will always start in the Idle step and then wait for a StepEnable[n] bit to turn on. After a step is enabled, the sequencer will start with the lowest step (1) and continue until step (16),. If a step is not enabled, then sequencer will skip to the next step. If all steps are disabled, then the sequencer will remain in the IDLE state and continue to apply the Idle StepConfig settings.

Assuming a touch screen only mode (no general purpose channels) the steps could be configured as HW synchronized triggered (mapped to the PEN event).. The sequencer would wait in the IDLE state until a HW pen down event occurred and then begin the HW step conversions. The Touch Screen Charge step occurs after the last HW step before going back to the Idle state (the TS Charge step is needed to charge touch screen capacitance which allows the controller to detect subsequent Pen touch events).

Assuming a mixed mode application (touch screen and general purpose channels), the user can configure the steps as either HW triggered (mapped to Pen event) or SW enabled. If the sequencer is in the IDLE state and a HW pen event occurs, then the HW steps (from lowest to highest) are always scheduled first, followed by the TS Charge step. If there is no HW event, then the SW enabled steps are scheduled instead

If a HW event occurs while the sequencer is in the middle of scheduling the SW steps, the user can program the scheduler to allow preemption. If the HW preempt control bit is enabled, the sequenceer will allow the current SW step to finish and then schedule the HW steps. After the last HW step and TS Charge step are completed, the sequencer will continue from the next SW step (before the preemption occurred). If the HW preemption is disabled, then the touch event will be ignored until the last software step is completed; if the touch event is removed before the last software step is finished, then the touch event will be missed.

Even if a touch screen is not present, the user can still configure the steps to be HW synchronize by mapping to the HW event input signal. This HW event input signal could be driven at the SOC level from a timer interrupt or some other IP and can be used to start a channel conversion.

When mapping is set for the input HW event signal, then the TSC_ADC_SS will wait for a rising edge transition (from low to high) before starting. The input HW event signal is captured on the internal L4 OCP clock domain. The HW event input signal should be held for at least 2 TSC_ADC_SS OCP clocks (L4 frequency).

An END_OF_SEQUENCE interrupt and the PEN_UP interrupt are generated after the last active step is completed before going back to the IDLE state. The END_OF_SEQUENCE interrupt does not mean data is in the FIFO (should use the FIFO interrupts and word count reg)

11.4.1 PenCtrl and PenIRQ

The Pen IRQ can only occur if the correct Pen Ctrl bits are high (AFE Pen Ctrl bits 6:5 in the TSC_ADC control register) and if the correct ground transistor biasing is set in the StepConfig [N] Register. Refer to the application notes for the correct settings.

If a step is configured as HW synchronized, the sequencer will override the PenCtrl bits set by the software (bits 6 and 5) once it transitions from the IdleStep. The sequencer will automatically mask the PenCtrl bits (override them and turn them off) so that the ADC can get an accurate measurement from the x and y channels. After the last HW synchronized step, the sequence will go to the TS Charge step and the pen_overide mask is removed and the values set by the SW (bits 6:5) will have control. The pen_irq will be temporarily ignored during the TS Charge step (Hw will mask any potential glitchs that may occur)

If the sequencer is not using the HW synchronized approach, (all the steps are configured as software enabled), then it is the software programmer's responsibility to correctly turn on and off the pen ctrl bits to the AFE in order get the correct measures from the touch screen. It is also software job to send the charge step and ignore any potential glitches (by using pen_irq status register).

It is also possible to detect the HW Pen event even if all the StepEnable[n] bits are off. By setting the PenCtrl bit to 1, and configuring the IdleStep Configuration register to correctly bias the transistor to grnd, the HW_PEN event will be generated. The flowchart for the sequencer is shown in Figure 11-3 and an example timing diagram in Figure 11-4.

Figure 11-3. Sequencer FSM

The previous diagram does not actually represent clock cycles but instead illustrates how the scheduler will work(however, each shaded box above does represent a FSM state and will use a clock cycle). Using the minimum delay values, the ADC can sample at 15 ADC clocks per sample. Below is an example timing diagram illustrating the states of the sequencer and also the showing when the StepConfig and the StepDelay registers values are applied. The below example assumes the steps are software controlled, and averaging is turned off.

Figure 11-4. Example Timing Diagram for Sequencer

The Idle StepConfig is always enabled and applied when the FSM is in the IDLE state (i.e, either waiting for a HW event or waiting for a step to be enabled). The Idle StepConfig can not be disabled.

Once the TSC_ADC_SS is enabled and assuming at least one StepEnable[N] is active, the FSM will transition from the Idle state and apply the first active StepConfig[N] and StepDelay[N] register settings. It is possible for the OpenDelay[N] value to be 0, and therefore the FSM will immediately skip to the SampleDelay[N] state (which is minimum 1 clock cycle). The ADC will begin the sampling on the falling edge of the SOC signal. After the ADC is finished converting the channel data (13 cycles later), the EOC signal is sent and the FSM will then apply the next active step [N+1].

This process is repeated and continued (from step 1 to step 16) until the last active step is completed.

11.5 TSC_ADC_SS Registers

Table 11-5 lists the memory-mapped registers for the TSC_ADC_SS. See your device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 11-5 should be considered as reserved locations and the register contents should not be modified.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 11-49. CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	Reserved	R	0h	
9	HW_preempt	R/W	0h	0->SW steps are not preempted by HW events 1-> SW steps are preempted by HW events
8	HW_event_mapping	R/W	0h	0->Map HW event to Pen touch irq (from AFE) 1->Map HW event to HW event input
7	Touch_Screen_Enable	R/W	0h	0 -> Touch Screen transistors disabled 1 -> TouchScreen transistors enabled
6-5	AFE_Pen_Ctrl	R/W	0h	These 2 bits are sent directly to the AFE Pen Ctrl inputs. Bit 6 controls the Wiper touch (5 wire modes)Bit 5 controls the X+ touch (4 wire modes)User also needs to make sure the ground path is connected properly for pen interrupt to occur (using the StepConfig registers)Refer to section 4 interrupts for more information
4	Power_Down	R/W	0h	ADC Power Down control 0: AFE is powered up (default) 1 : Write 1 to power down AFE (the tsc_adc_ss enable (bit 0) should also be set to off)
3	ADC_Bias_Select	R/W	0h	Select Internal or External Bias to AFE 0 -> Internal 1 -> External
2	StepConfig_WriteProtect_n_active_low	R/W	0h	0-> Step Configuration Registers are protected (not writable) 1-> Step Configuration are not protected (writable)
1	Step_ID_tag	R/W	0h	Writing 1 to this bit will store the Step ID number with the captured ADC data in the FIFO. 0 write zeros1 store the channel id tag
0	Enable	R/W	0h	TSC_ADC_SS module enable bit. After programming all the steps and configuration registers, write a 1 to this bit to turn on TSC_ADC_SS. Writing a 0 will disable the module (after the current conversion)

12.1 Introduction

12.1.1 Purpose of the Peripheral

The LCD controller consists of two independent controllers, the Raster Controller and the LCD Interface Display Driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The Raster Controller handles the synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale/serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. A built-in DMA engine supplies the graphics data to the Raster engine which, in turn, outputs to the external LCD device.
- The LIDD Controller supports the asynchronous LCD interface. It provides full-timing programmability of control signals (CS, WE, OE, ALE) and output data.

Figure 12-1 shows the LCD controller details. The raster and LIDD Controllers are responsible for generating the correct external timing. The DMA engine provides a constant flow of data from the frame buffer(s) to the external LCD panel via the Raster and LIDD Controllers. In addition, CPU access is provided to read and write registers.

The solid, thick lines in Figure 12-1 indicate the data path. The Raster Controller's data path is fairly complicated, for a thorough description of the Raster Controller data path, see Section 12.3.5.

Figure 12-1. LCD Controller

12.1.2 Features

General features of the LCD Controller include:

- Supports up to 24-bits data output; 8 bits-per-pixel (RGB).
- Supports up to WXGA resolution.
- Integrated DMA engine to pull data from the external frame buffer without burdening the processor via interrupts or a firmware timer.
- 512 word deep internal FIFO with programmable threshold values.
- Character Based Panels
  - Supports 2 Character Panels (CS0 and CS1) with independent and programmable bus timing parameters when in asynchronous Hitachi, Motorola and Intel modes
  - Supports 1 Character Panel (CS0) with programmable bus timing parameters when in synchronous Motorola and Intel modes
  - Can be used as a generic 16 bit address/data interleaved MPU bus master with no external stall
- Passive Matrix LCD Panels
  - Panel types including STN, DSTN, and C-DSTN
  - AC Bias Control
- Active Matrix LCD Panels
  - Panel types including TN TFT
- OLED Panels
  - Passive Matrix (PM OLED) with frame buffer and controller IC inside the Panel
  - Active Matrix (AM OLED)

12.1.3 Unsupported Features

The LCD Controller does not support resolutions above WXGA due to IO timing limitations.

12.2 Integration

The device includes an LCD Controller that reads display data from external memory and drives several different types of LCD displays. The LCD Controller integration is shown in Figure 12-2.

Figure 12-2. LCD Controller Integration

12.2.1 LCD Controller Connectivity Attributes

The general connectivity attributes for the LCDC subsystems are shown in Table 12-1.

Table 12-1. LCD Controller Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_LCD_L3_GCLK (OCP Master Clock) PD_PER_LCD_L3_GCLK (OCP Slave Clock) PD_PER_LCD_GCLK (Functional Clock)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Standby Smart Idle
Interrupt Requests	1 Interrupt to MPU Subsystem
DMA Requests	None
Physical Address	L4 Peripheral Slave Port

12.2.2 LCD Controller Clock and Reset Management

The LCDC module uses the following functional and OCP interface clocks. The L4 Slave interface runs at half the frequency of the L3 Master interface but uses the same clock. The clock is divided within the LCDC through the l4_clkdiv input using the pd_per_lcd_l4s_gclk_ien signal from the PRCM. The functional clock comes from the Display PLL. When the Display PLL is in bypass mode, it's output is sourced by either CORE_CLKOUTM6 or PER_CLKOUTM2.

Table 12-2. LCD Controller Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
l3_clk Master Interface Clock	200 MHz	CORE_CLKOUTM4	pd_per_lcd_l3_gclk From PRCM
l4_clk Slave Interface Clock	100 MHz	CORE_CLKOUTM4 (divided within LCDC)	pd_per_lcd_l3_gclk From PRCM
lcd_clk Functional Clock	200 MHz	Display PLL CLKOUT	pd_per_lcd_gclk From PRCM

12.2.3 LCD Controller Pin List

The LCD Controller external interface signals are shown in Table 12-3.

Table 12-3. LCD Controller Pin List

Pin	Type	Description
lcd_cp	O	Pixel Clock in Raster model Read Strobe or Read/Write Strobe in LIDD mode
lcd_pixel_i[15:0]	I	LCD Data Bus input (for LIDD mode only)
lcd_pixel_o[23:0]	O	LCD Data Bus output
lcd_lp	O	Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode
lcd_fp	O	Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode
lcd_ac	O	AC bias or Latch Enable in Raster mode; Primary Chip Select/Primary Enable in LIDD MPU/Hitachi mode
lcd_mclk	O	N/A in Raster mode; Memory Clock/Secondary chip Select/Secondary Enable in LIDD Synchronous/Async MPU/Hitachi mode

12.3 Functional Description

12.3.1 Clocking

This section details the various clocks and signals. Figure 12-3 shows input and output LCD controller clocks.

Figure 12-3. Input and Output Clocks

12.3.1.1 Pixel Clock

The pixel clock (LCD_PCLK) frequency is derived from LCD_CLK, the reference clock to this LCD module (see Figure 12-3). The pixel clock is used by the LCD display to clock the pixel data into the line shift register.

$$\text{LCD_PCLK} = \frac{\text{LCD_CLK}}{\text{CLKDIV}}$$

where CLKDIV is a field in the LCD_CTRL register and should not be 0 or 1.

- **Passive (STN) mode.** LCD_PCLK only transitions when valid data is available for output. It does not transition when the horizontal clock is asserted or during wait state insertion.
- **Active (TFT) mode.** LCD_PCLK continuously toggles as long as the Raster Controller is enabled.

DRAFT ONLY

Copyright © 2011, Texas Instruments Incorporated

12.3.1.2 Horizontal Clock (LCD_HSYNC)

LCD_HSYNC toggles after all pixels in a horizontal line have been transmitted to the LCD and a programmable number of pixel clock wait states has elapsed both at the beginning and end of each line.

The RASTER_TIMING_0 register fully defines the behavior of this signal.

LCD_HSYNC can be programmed to be synchronized with the rising or falling edge of LCD_PCLK. The configuration field is bits 24 and 25 in the RASTER_TIMING_2 register.

- **Active (TFT) mode.** The horizontal clock or the line clock is also used by TFT displays as the horizontal synchronization signal (LCD_HSYNC).

  The timings of the horizontal clock(line clock) pins are programmable to support:
- Delay insertion both at the beginning and end of each line
- Line clock polarity.
- Line clock pulse width, driven on rising or falling edge of pixel clock.

12.3.1.3 Vertical Clock (LCD_VSYNC)

LCD_VSYNC toggles after all lines in a frame have been transmitted to the LCD and a programmable number of line clock cycles has elapsed both at the beginning and end of each frame.

The RASTER_TIMING_1 register fully defines the behavior of this signal.

LCD_VSYNC can be programmed to be synchronized with the rising or falling edge of LCD_PCLK. The configuration field is bits 24 and 25 in the RASTER_TIMING_2 register.

- **Passive (STN) mode.** The vertical clock; that is, the frame clock, toggles during the first line of the screen.
- **Active (TFT) mode.** The vertical clock, that is, the frame clock, is also used by TFT displays as the vertical synchronization signal (LCD_VSYNC).

  The timings of the vertical clock pins are programmable to support:
- Delay insertion both at the beginning and end of each frame
- Frame clock polarity

12.3.1.4 $\overline{\text{LCD_AC_ENB_CS}}$

- **Passive (STN) mode.** To prevent a dc charge within the screen pixels, the power and ground supplies of the display are periodically switched. The Raster Controller signals the LCD to switch the polarity by toggling this pin ($\overline{\text{LCD_AC_ENB_CS}}$).
- **Active (TFT) mode.** This signal acts as an output enable (OE) signal. It is used to signal the external LCD that the data is valid on the data bus (LCD_D[15:0]). (see Figure 12-25)

12.3.2 LCD External I/O Signals

Table 12-4 shows the details of the LCD controller external signals.

Table 12-4. LCD External I/O Signals

Signal	Type	Description
LCD_VSYNC	OUT	Raster controller: Frame clock the LCD uses to signal the start of a new frame of pixels. Also used by TFT displays as the vertical synchronization signal. LIDD character: Register select (RS) or address latch enable (ALE) LIDD graphics: Address bit 0 (A0) or command/data select (C/D)
LCD_HSYNC	OUT	Raster controller: Line clock the LCD uses to signal the end of a line of pixels that transfers line data from the shift register to the screen and to increment the line pointer(s). Also used by TFT displays as the horizontal synchronization signal. LIDD character: not used. LIDD graphics: • 6800 mode = read or write enable • 8080 mode = not write strobe
LCD_PCLK	OUT	Raster controller: Pixel clock the LCD uses to clock the pixel data into the line shift register. In passive mode, the pixel clock transitions only when valid data is available on the data lines. In active mode, the pixel clock transitions continuously, and the ac-bias pin is used as an output enable to signal when data is available on the LCD pin. LIDD character: not used. LIDD graphics: • 6800 mode = enable strobe • 8080 mode = not read strobe
$\overline{\text{LCD_AC_ENB_CS}}$	OUT	Raster controller: ac-bias used to signal the LCD to switch the polarity of the power supplies to the row and column axis of the screen to counteract DC offset. Used in TFT mode as the output enable to signal when data is latched from the data pins using the pixel clock. LIDD character: Primary enable strobe LIDD graphics: Chip select 0 (CS0)
LCD_MCLK	OUT	Raster controller: not used. LIDD character: Secondary enable strobe LIDD graphics: Chip select 1 (CS1)
LCD_D[15:0]	Raster: OUT	LCD data bus, providing a 4-, 8-, or 16-bit data path.
	LIDD: OUT/IN	Raster controller: For monochrome displays, each signal represents a pixel; for passive color displays, groupings of three signals represent one pixel (red, green, and blue). LCD_D[3:0] is used for monochrome displays of 2, 4, and 8 BPP; LCD_D[7:0] is used for color STN displays and LCD_D[15:0] is used for active (TFT) mode. LIDD character: Read and write the command and data registers. LIDD graphics: Read and write the command and data registers.

12.3.3 DMA Engine

The DMA engine provides the capability to output graphics data to constantly refresh LCDs, without burdening the CPU, via interrupts or a firmware timer. It operates on one or two frame buffers, which are set up during initialization. Using two frame buffers (ping-pong buffers) enables the simultaneous operation of outputting the current video frame to the external display and updating the next video frame. The ping-pong buffering approach is preferred in most applications.

When the Raster Controller is used, the DMA engine reads data from a frame buffer and writes it to the input FIFO (as shown in Figure 12-1). The Raster Controller requests data from the FIFO for frame refresh; as a result, the DMA's job is to ensure that the FIFO is always kept full.

When the LIDD Controller is used, the DMA engine accesses the LIDD Controller's address and/or data registers.

To program DMA engine, configure the following registers, as shown in Table 12-5.

Table 12-5. Register Configuration for DMA Engine Programming

Register	Configuration
LCDDMA_CTRL	Configure DMA data format
LCDDMA_FB0_BASE LCDDMA_FB0_CEILING	Configure frame buffer 0
LCDDMA_FB1_BASE LCDDMA_FB1_CEILING	Configure frame buffer 1. (If only one frame buffer is used, these two registers will not be used.)

In addition, the LIDD_CTRL register (for LIDD Controller) or the RASTER_CTRL register (for Raster Controller) should also be configured appropriately, along with all the timing registers.

To enable DMA transfers, the LIDD_DMA_EN bit (in the LIDD_CTRL register) or the LCDEN bit (in the RASTER_CTRL register) should be written with 1.

12.3.3.1 Interrupts

Interrupts in this LCD module are related to DMA engine operation. Three registers are closely related to this subject:

- The LIDD_CTRL and RASTER_CTRL registers enable or disable each individual interrupt sources.
- The LCD_STAT register collects all the interrupt status information.

12.3.3.1.1 LIDD Mode

When operating in LIDD mode, the DMA engine generates one interrupt signal every time the specified frame buffer has been transferred completely.

- The DONE_INT_EN bit in the LIDD_CTRL register specifies if the interrupt signal is delivered to the system interrupt controller, which in turn may or may not generate an interrupt to CPU.
- The EOF1, EOF0, and DONE bits in the LCD_STAT register reflect the interrupt signal, regardless of being delivered to the system interrupt controller or not.

12.3.3.1.2 Raster Mode

When operating in Raster mode, the DMA engine can generate the interrupts in the following scenarios:

1. **Output FIFO under-run**. This occurs when the DMA engine cannot keep up with the data rate consumed by the LCD (which is determined by the LCD_PCLK.) This is likely due to a system memory throughput issue or an incorrect LCD_PCLK setting. The FUF bit in LCD_STAT is set when this error occurs. This bit is cleared by disabling the Raster Controller (i.e., clearing the LCDEN bit in RASTER_CTRL).

Copyright © 2011, Texas Instruments Incorporated

2. **Frame synchronization lost**. This error happens when the DMA engine attempts to read what it believes to be the first word of the video buffer but it cannot be recognized as such. This could be caused by an invalid frame buffer address or an invalid BPP value (for more details, see Section 12.3.5.2). The SYNC bit in the LCD_STAT register is set when such an error is detected. This field is cleared by disabling the Raster Controller (clearing the LCDEN bit in the RASTER_CTRL register).
3. **Palette loaded**. This interrupt can be generated when the palette is loaded into the memory by the DMA engine. At the same time, the PL bit in the LCD_STAT register is set. In data-only (PLM = 2h) and palette-plus-data (PLM = 00) modes, writing 0 to this bit clears the interrupt. In the palette-only (PLM = 1) mode, this bit is cleared by disabling the Raster Controller (clearing the LCDEN bit in the RASTER_CTRL register).
4. **AC bias transition**. If the ACB_I bit in the RASTER_TIMING_2 register is programmed with a non-zero value, an internal counter will be loaded with this value and starts to decrement each time $\overline{\text{LCD_AC_ENB_CS}}$ (AC-bias signal) switches its state. When the counter reaches zero, the ABC bit in the LCD_STAT register is set, which will deliver an interrupt signal to the system interrupt controller (if the interrupt is enabled.) The counter reloads the value in field ACB_I, but does not start to decrement until the ABC bit is cleared by writing 0 to this bit.
5. **Frame transfer completed**. When one frame of data is transferred completely, the DONE bit in the LCD_STAT register is set. This bit is cleared by disabling the Raster Controller (i.e., clearing the LCDEN bit in the RASTER_CTRL register). Note that the EOF0 and EOF1 bits in the LCD_STAT register will be set accordingly.

Note that the interrupt enable bits are in the RASTER_CTRL register. The corresponding enable bit must be set in order to generate an interrupt to the CPU. However, the LCD_STAT register reflects the interrupt signal regardless of the interrupt enable bits settings.

12.3.3.1.3 Interrupt Handling

Refer the device-specific data manual for information about LCD interrupt number to CPU .The interrupt service routine needs to determine the interrupt source by examining the LCD_STAT register and clearing the interrupt properly.

12.3.4 LIDD Controller

The LIDD Controller is designed to support LCD panels with a memory-mapped interface. The types of displays range from low-end character monochrome LCD panels to high-end TFT smart LCD panels.

LIDD mode (and the use of this logic) is enabled by clearing the MODESEL bit in the LCD control register (LCD_CTRL).

LIDD Controller operation is summarized as follows:

- During initialization, the LCD LIDD CS0/CS1 configuration registers (LIDD_CS0_CONF and LIDD_CS1_CONF) are configured to match the requirements of the LCD panel being used.
- During normal operation, the CPU writes display data to the LCD data registers (LIDD_CS0_DATA and LIDD_CS1_DATA). The LIDD interface converts the CPU write into the proper signal transition sequence for the display, as programmed earlier. Note that the first CPU write should send the beginning address of the update to the LCD panel and the subsequent writes update data at display locations starting from the first address and continuing sequentially. Note that DMA may be used instead of CPU.
- The LIDD Controller is also capable of reading back status or data from the LCD panel, if the latter has this capability. This is set up and activated in a similar manner to the write function described above.

NOTE: If an LCD panel is not used, this interface can be used to control any MCU-like peripheral.

See your device-specific data manual to check the LIDD features supported by the LCD controller.

Table 12-6 describes how the signals are used to interface external LCD modules, which are configured by the LIDD_CTRL register.

Copyright © 2011, Texas Instruments Incorporated

Table 12-6. LIDD I/O Name Map

Display Type	Interface Type	Data Bits	LIDD_CTRL [2:0]	I/O Name	Display I/O Name	Comment
Character Display	HD44780 Type	4	100	LCD_D[7:4]	DATA[7:4]	Data Bus (length defined by Instruction)

				LCD_HSYNC	R/$\overline{W}$	Read/$\overline{Write}$
				LCD_VSYNC	RS	Register Select (Data/not Instruction)
				LCD_MCLK	E1	Enable Strobe (second display optional)
Character Display	HD44780 Type	8	100	LCD_D[7:0]	DATA[7:0]	Data Bus (length defined by Instruction)
				LCD_PCLK	E (or E0)	Enable Strobe (first display)
				LCD_HSYNC	R/$\overline{W}$	Read/$\overline{Write}$
				LCD_VSYNC	RS	Register Select (Data/not Instruction)
				LCD_MCLK	E1	Enable Strobe (second display optional)
Micro Interface Graphic Display	6800 Family	Up to 16	001	LCD_D[15:0]	DATA[7:0]	Data Bus (16 bits always available)
				LCD_PCLK	E	Enable Clock
				LCD_HSYNC	R/$\overline{W}$	Read/$\overline{Write}$
				LCD_VSYNC	A0	Address/Data Select
				$\overline{LCD_AC_ENB_CS}$	CS (or CS0)	Chip Select (first display)
				LCD_MCLK	CS1	Chip Select (second display optional)
			000	LCD_MCLK	None	Synchronous Clock (optional)
Micro Interface Graphic Display	8080 Family	Up to 16	011	LCD_D[15:0]	DATA[7:0]	Data Bus (16 bits always available)
				LCD_PCLK	RD	Read Strobe
				LCD_HSYNC	WR	Write Strobe
				LCD_VSYNC	A0	Address/Data Select
				$\overline{LCD_AC_ENB_CS}$	CS (or CS0)	Chip Select (first display)
				LCD_MCLK	CS1	Chip Select (second display optional)
			010	LCD_MCLK	None	Synchronous Clock (optional)

The timing parameters are defined by the LIDD_CS0_CONF and LIDD_CS1_CONF registers, which are described in Section 12.5.7.

The timing configuration is based on an internal reference clock, MCLK. The MCLK is generated out of LCD_CLK, which is determined by the CLKDIV bit in the LCD_CTRL register.

$$\text{MCLK} = \text{LCD_CLK when CLKDIV} = 0.$$

$$\text{MCLK} = \frac{\text{LCD_CLK}}{\text{CLKDIV}} \text{ when CLKDIV} \neq 0.$$

See your device-specific data manual for the timing configurations supported by the LCD controller.

12.3.5 Raster Controller

Raster mode (and the use of this logic) is enabled by setting the MODESEL bit in the LCD control register (LCD_CTRL). Table 12-7 shows the active external signals when this mode is active.

Table 12-7. Operation Modes Supported by Raster Controller

Interface	Data Bus Width	Register Bits RASTER_CTRL[9, 7, 1]	Signal Name	Description
Passive (STN) Mono 4-bit	4	001	LCD_D[3:0]	Data bus
			LCD_PCLK	Pixel clock
			LCD_HSYNC	Horizontal clock(Line Clock)
			LCD_VSYNC	Vertical clock (Frame Clock)
			$\overline{\text{LCD_AC_ENB_CS}}$	AC Bias
			LCD_MCLK	Not used
Passive (STN) Mono 8-bit	8	101	LCD_D[7:0]	Data bus
			LCD_PCLK	Pixel clock
			LCD_HSYNC	Horizontal clock(Line Clock)
			LCD_VSYNC	Vertical clock (Frame Clock)
			$\overline{\text{LCD_AC_ENB_CS}}$	AC Bias
			LCD_MCLK	Not used
Passive (STN) Color	8	100	LCD_D[7:0]	Data bus
			LCD_PCLK	Pixel clock
			LCD_HSYNC	Horizontal clock(Line Clock)
			LCD_VSYNC	Vertical clock (Frame Clock)
			$\overline{\text{LCD_AC_ENB_CS}}$	AC Bias
			LCD_MCLK	Not used
Active (TFT) Color	16	x10	LCD_D[15:0]	Data bus
			LCD_PCLK	Pixel clock
			LCD_HSYNC	Horizontal clock(Line Clock)
			LCD_VSYNC	Vertical clock (Frame Clock)
			$\overline{\text{LCD_AC_ENB_CS}}$	Output enable
			LCD_MCLK	Not used

12.3.5.1 Logical Data Path

The block diagram of the Raster Controller is shown in Figure 12-1. Figure 12-12 illustrates its logical data path for various operation modes (passive (STN) versus active (TFT), various BPP size).

Figure 12-12 shows that:

- The gray-scaler/serializer and output FIFO blocks are bypassed in active (TFT) modes.
- The palette is bypassed in both 12- and 16-BPP modes.

Figure 12-12. Logical Data Path for Raster Controller

In summary:

- The display image is stored in frame buffers.
- The built-in DMA engine constantly transfers the data stored in the frame buffers to the Input FIFO.
- The Raster Controller relays data to the external pins according to the specified format.

The remainder of this section describes the functioning blocks in Figure 12-12, including frame buffers, palette, and gray-scaler/serializer. Their operation and programming techniques are covered in detail. The output format is also described in Section 12.3.5.5.

12.3.5.2 Frame Buffer

A frame buffer is a contiguous memory block, storing enough data to fill a full LCD screen. For this device, external memory needs to be used for the frame buffer. For specific details on which external memory interface (EMIF) controller can be accessed by the LCD controller, see your device-specific data manual. The data in the frame buffer consists of pixel values as well as a look-up palette. Figure 12-13 shows the frame buffer structure.

Figure 12-13. Frame Buffer Structure

1, 2, 4, 12, 16 BPP Modes

8 BPP Mode

NOTE:

- 8-BPP mode uses the first 512 bytes in the frame buffer as the palette while the other modes use 32 bytes.
- 12- and 16-BPP modes do not need a palette; i.e., the pixel data is the desired RGB value. However, the first 32 bytes are still considered a palette. The first entry should be 4000h (bit 14 is 1) while the remaining entries must be filled with 0. (For details, see Table 12-8.)
- Each entry in a palette occupies 2 bytes. As a result, 8-BPP mode palette has 256 color entries while the other palettes have up to 16 color entries.
- 4-BPP mode uses up the all the 16 entries in a palette.
- 1-BPP mode uses the first 2 entries in a palette while 2-BPP mode uses the first 4 entries. The remaining entries are not used and must be filled with 0.
- In 12- and 16-BPP modes, pixel data is RGB data. For all the other modes, pixel data is actually an index of the palette entry.

Table 12-8. Bits-Per-Pixel Encoding for Palette Entry 0 Buffer

Bit	Name	Value	Description [(1)] [(2)]
14-12	BPP		Bits-per-pixel.
		000	1 BPP
		001	2 BPP
		010	4 BPP
		011	8 BPP
		1xx	12 BPP in passive mode (TFT_STN = 0 and STN_565 = 0 in RASTER_CTRL)
			16 BPP in passive mode (TFT_STN = 0 and STN_565 = 1 in RASTER_CTRL)
			16 BPP in active mode (TFT_STN = 1 in RASTER_CTRL)

(1) Eight 1-bit pixels, four 2-bit pixels, and two 4-bit pixels are packed into each byte, and 12-bit pixels are right justified on (16-bit) word boundaries (in the same format as palette entry).

(2) For STN565, see the 16 BPP STN mode bit ().

The equations shown in Table 12-9 are used to calculate the total frame buffer size (in bytes) based on varying pixel size encoding and screen sizes.

Figure 12-14 and Figure 12-15 show more detail of the palette entry organization.

Table 12-9. Frame Buffer Size According to BPP

BPP	Frame Buffer Size
1	32 + (Lines × Columns)/8
2	32 + (Lines × Columns)/4
4	32 + (Lines × Columns)/2
8	512 + (Lines × Columns)
12/16	32 + 2 × (Lines × Columns)

Figure 12-14. 16-Entry Palette/Buffer Format (1, 2, 4, 12, 16 BPP)

A. Bits-per-pixels (BPP) is only contained within the first palette entry (palette entry 0).

256-Entry Palette Buffer

Bit	15 … 0
Base + 0	Palette Entry 0
Base + 2	Palette Entry 1
. . .	. . .
Base + FCh	Palette Entry 254
Base + FEh	Palette Entry 255

A. Bits-per-pixels (BPP) is only contained within the first palette entry (palette entry 0).

Bits 12, 13, and 14 of the first palette entry select the number of bits-per-pixel to be used in the following frame and thus the number of palette RAM entries. The palette entry is used by the Raster Controller to correctly unpack pixel data.

The following figures show the memory organization within the frame buffer for each pixel encoding size.

12.3.5.3 Palette

As explained in the previous section, the pixel data is an index of palette entry (when palette is used). The number of colors supported is given by $2^{\text{number of BPP}}$. However, due to a limitation of the gray-scaler/serializer block, fewer grayscales or colors may be supported.

The PLM field (in RASTER_CTRL) affects the palette loading:

- If PLM is 00b (palette-plus-data mode) or 01b (palette-only mode), the palette is loaded by the DMA engine at the very beginning, which is followed by the loading of pixel data.
- If PLM is 10b (data-only mode), the palette is not loaded. Instead, the DMA engine loads the pixel data immediately.

12.3.5.4 Gray-Scaler/Serializer

12.3.5.4.1 Passive (STN) Mode

Once a palette entry is selected from the look-up palette by the pixel data, its content is sent to the gray-scaler/serializer. If it is monochrome data, it is encoded as 4 bits. If it is color data, it is encoded as 4 bits (Red), 4 bits (Green), and 4 bits (Blue).

These 4-bit values are used to select one of the 16 intensity levels, as shown in Table 12-10. A patented algorithm is used during this processing to provide an optimized intensity value that matches the eye's visual perception of color/gray gradations.

12.3.5.4.2 Active (TFT) Mode

The gray-scaler/serializer is bypassed.

Table 12-10. Color/Grayscale Intensities and Modulation Rates

Dither Value (4-Bit Value from Palette)	Intensity (0% is White)	Modulation Rate (Ratio of ON to ON+OFF Pixels)
0000	0.0%	0
0001	11.1%	1/9
0010	20.0%	1/5
0011	26.7%	4/15
0100	33.3%	3/9
0101	40.0%	2/5
0110	44.4%	4/9
0111	50.0%	1/2
1000	55.6%	5/9
1001	60.0%	3/5
1010	66.6%	6/9
1011	73.3%	11/15
1100	80.0%	4/5
1101	88.9%	8/9
1110	100.0%	1
1111	100.0%	1

12.3.5.4.3 Summary of Color Depth

Table 12-11. Number of Colors/Shades of Gray Available on Screen

Number of BPP	Passive Mode (TFT_STN = 0)		Active Mode (TFT_STN = 1)
	Monochrome (MONO_COLOR = 1)	Color (MONO_COLOR = 0)	Color Only (MONO_COLOR = 0)
1	2 palette entries to select within 15 grayscales	2 palette entries to select within 3375 possible colors	2 palette entries to select within 4096 possible colors
2	4 palette entries to select within 15 grayscales	4 palette entries to select within 3375 possible colors	4 palette entries to select within 4096 possible colors
4	16 palette entries to select within 15 grayscales	16 palette entries to select within 3375 possible colors	16 palette entries to select within 4096 possible colors
8	Not relevant since it would consist in 256 palette entries to select within 15 grayscales, but exists anyway	256 palette entries to select 3375 possible colors	256 palette entries to select within 4096 possible colors
12	x	3375 possible colors	4096 possible colors
16	x	3375 possible colors (STN_565 = 1)	Up to 65536 possible colors

12.3.5.5 Output Format

12.3.5.5.1 Passive (STN) Mode

As shown in Figure 12-12, the pixel data stored in frame buffers go through palette (if applicable) and gray-scaler/serializer before reaching the Output FIFO. As a result, it is likely that the data fed to the Output FIFO is numerically different from the data in the frame buffers. (However, they represent the same color or grayscale.)

The output FIFO formats the received data according to display modes (see Table 12-7). Figure 12-22 shows the actual data output on the external pins.

12.3.5.5.2 Active (TFT) Mode

As shown in Figure 12-12, the gray-scaler/serializer and output FIFO are bypassed in active (TFT) mode. Namely, at each pixel clock, one pixel data (16 bits) is output to the external LCD.

12.3.5.6 Subpanel Feature

In some applications, it is desired to display only the first or last few lines of the LCD panel (see Figure 12-23). This is mainly used for power saving.

This is supported by the Raster Controller via its subpanel feature. The RASTER_SUBPANEL register fully defines its behavior, that is, the following parameters are defined:

- Whether the first or last few lines will be refreshed.
- A line number, which is the last (or first) line to be refreshed.
- The pixel data to be loaded to the refresh area.

Note that there is only one pixel value for all the pixels in the refresh area. As a result, frame buffers and DMA engine are not used in this case, which leads to power saving.
